The conception can be extended^o to all zones delimiting two constituents in ternary diagrams. Up to the present it has been considered only for special brasses. This is due to the fact that in these alloys the modifications of the properties are closely dependent upon the ratio of components and that the addition of a third metal to an ordinary binary brass is marked micrographically by a variation in the ratio of its two micrographic constituents.

In the case when three constituents are present, due to a defined reaction among four phases, the question of isomicrographic lines refers only to two of the three constituents.

Uniformity of Digester Chip Charges*

How uniform are the weights of wood in the digester charge, the unit commonly used in chemical pulp-mill operation, is indicated by data obtained in a millscale. For a period of three months at a certain mill it was possible to weigh all the chips entering one digester, to make accurate determinations of their moisture content, and so to compute the actual amount of wood substance in each charge.

The chip charges for thirty-eight cooks showed the following variation in weight, after deducting for moisture:

- 7 charges weighed between 11,600 and 12,600 lb.
- 24 charges weighed between 12,600 and 13,600 lb.
- 7 charges weighed between 13,600 and 14,600 lb.

Fifty per cent of the charges contained between 13,000 and 13,770 lb. of chips—a variation in weight within the limits of $\pm 2\frac{1}{2}$ per cent. Delays of more than twenty-four hours occurred in starting all the cooks with charges of more than 13,770 lb.; and since it was customary before bolting down the cover to fill with additional chips the space left by the settling of the charge, the longer filling periods account for the larger amounts of wood in these charges. The cooks with charges of less than 12,600 lb. were started without refilling after the liquor charge was added, and it was expected that they would be light.

The weighting experiments indicate that the digester charge is, in most instances, a reliable unit for pulp-mill operation, provided the operation is uninterrupted and the soundness and species of pulpwood do not vary.

Vegetable Seed Oil Extraction in Argentina

Linseed oil has for some time been an item in the Argentine exports. Great quantities of the seed are harvested annually and enough has been elaborated to satisfy the requirements of the domestic paint manufacturers as well as those of neighboring countries. For various reasons the principal consuming countries have preferred to purchase the seed for transportation to their own mills, but there is now in the process of construction near Rosario what is said to be the largest grinding plant in existence, reports Trade Commissioner P. S. Smith. It is owned by the Compañía Sud Americana de Cereales, a Dutch concern, which intends to produce various kinds of oil and ship both it and the cake to Europe.

Castor oil is also produced in appreciable quantities for industrial and medicinal purposes. Rape seed is found to be mixed with linseed and both it and colewort seed are worked for their oil content.

Cotton seed is not abundant as yet, but it is expected that the supply will be materially augmented each year from now on as a result of the increased acreage planted to cotton in the Territory of El Chaco. One new mill especially adapted for the production of cottonseed oil is being put up this year; in fact, all of the present plants elaborate the seed on a small scale.

Peanut oil is growing in importance, both it and cottonseed oil being employed locally to replace in part the imports of edible oils from Europe and the United States.

Olives have been grown in an experimental way in the Province of La Rioja and oil has been obtained from the native fruit, but future development along this line does not give promise of being rapid.

Corn oil is made by two companies, although the output as yet is insignificant with relation to the world's production.

A few of the plants extract the oil by solution, using either benzene or trichlorethylene as the solvent, following a well-known French process. The remaining mills employ vertical hydraulic presses of varying capacities and degrees of efficiency.

In general the oil-expelling plants are quite well equipped with machinery, although in some the seed-grinding apparatus could be improved. As the demand is small, the supplies are bought from local stores.

Effect of Mechanical Treatment Upon the Properties of Steel

The properties of steel and many other alloys are largely determined by three factors: composition, including structure; heat-treatment, and mechanical treatment. On account of the lack of suitable apparatus for the investigation of the last-named factor, this subject has received rather scant attention in the experimental study of steel. For this reason quite an elaborate study of the rolling of steel has been undertaken by the Bureau of Standards, where the special facilities—such as the small rolling mill—have proved to be of great value.

The investigation has been completed as far as the rolling operations are concerned and the test specimens are now being prepared for the different mechanical tests which together with other examinations—such as metallographic—will be used as a measure of the effect of the various factors which enter into the mechanical treatment of metals.

Cloths for Mechanical Uses*

The Specific Mechanical Purposes for Which Cloths Are Used and an Enumeration of Their Applications in the Most Important Industries

BY JAMES W. COX, JR.†

CLOTHS for mechanical uses are made from practically all the well-known fibers, cotton predominating, with wool, asbestos, silk and linen following in about the order named. Occasionally other fibers are used in cloth for special purposes. Cloth is used for mechanical purposes where it only will function or as a substitute for leather, metal banding, metal cloth, rawhide, sheet metal, wire or wire screen. Cost is usually the principal consideration for substituting cloth for the above materials; also it has been found in many instances that a fabric did the work in a better manner than the original substances, flexibility being a large factor in its adoption.

These cloths can be classified as to specific uses and to different industrial groups. It is impossible in one paper to give every specific use of mechanical cloths. The following tabulation, however, roughly covers their most common uses:

Absorption	Facings	Partitioning
Aprons	Fabric bases	Patching (repair)
Backings	Filters	Polishing
Bagging	Flame protectors	Pressing
Belts	Formers	Screens
Binders	Gaskets	Sieves
Buffers	Grips	Slings
Bumpers	Hose	Steaming
Cabling	Inking	Straps
Carriers	Insulating	Tapes
Cleaners	Jacketing	Tracing
Conveyors	Laminated materials	Tubing
Covers	Leaders (machine)	Washers
Containers	Linings	Webbing
Cushion devices	Marking	Wicks
Curtaining	Moistening	Windings
Distributors	Packing	
Drying	Paddings	

Practically every industry uses cloth mechanically in some way, those listed below being the largest and perhaps the most prominent consumers:

Aircraft	Farm machinery	Paper
Army	Flour	Powder
Automobile	Gas manufacture	Printing
Baking	Household machinery	Pumping
Beverage	Laundry machinery	Railroads
Candy	Mining	Rubber
Canning	Musical instruments	Shipbuilding
Chemical	Office machinery	Shoe machinery
Conveyor	Oil	Textile
Electrical	Packing, mechanical	
Engraving	Paint	

Specific Uses

BELTING

Woven belts are made for practically every purpose a leather belt is used for, including conveyors and machine aprons. Woven belting is being used plain, or impregnated with various substances such as tar, rubber

and materials of this type. It has the advantages of being more nearly heat-, gas-, moisture- and water-proof and is usually cheaper. Belts of this type are made wholly of cotton, or if excessive strength is required the warp is of camel's hair. In general they are made from two- to eight-ply plain fabric formed like a webbing and resembling before treatment a heavy, thick, narrow duck.

Belts of canvas or light duck in two-ply and up are also made by stitching the length of the belt every half-inch or so apart. Then this is treated or impregnated in the same way as the solid-woven fabric.

ABSORPTIVES

Coarse plain-woven jute and cotton cloth are used for this purpose. In either case the material is impregnated chemically so that when put in a machine, room or mine it will absorb gases of various kinds, moisture, etc. Cloth for absorption purposes is generally known as "brattice cloth." Jute was almost universally used until the price mounted; now low grades of cotton and cotton waste are used to a large extent as a substitute.

BINDINGS AND CHECK STRAPS

Heavy cotton webbing is used on various types of machines for lifting mechanisms. It is used in loop form on automobiles to prevent the too rapid recoil of the springs, also in special patented devices to achieve the same purpose. It is used for check straps on machines, train signals, and in street and railroad cars. Impregnated, light cotton tape is used for making various pipe connections and in electrical wire splices.

CONVEYING

Cotton duck, from light army to heavy numbered, is used extensively in conveying machinery of all kinds. Camel's-hair, plain cotton and stitched canvas belting is also used either treated or plain, according to the conditions under which the conveyor is run. The widths and weights vary from a cotton webbing for conveying small machine parts, to a heavy double- or triple-width belt for a box, barrel, coal or iron conveyor, etc. In two industries, candy making and photographic-film making, cotton oilcloth is used on account of its smoothness and ease of cleansing.

FILTERING

The filtering or straining of gases, air and liquids is considered under this head, the sifting of solids being taken up under "Sieves." In some cases when the filtration is slow and the pressure great the process is known as "pressing," but the action is identically the same, taking out substances that are not desired.

In the manufacture of some commercial gases a fine

*Reprinted from *Mechanical Engineering*, vol. 43, p. 177, March, 1921.

†Textile Engineer, New York, N. Y.

plain-woven linen, cotton or woolen cloth is used to take out solid particles of matter which are occasionally present. Fine asbestos cloth is also used when a detrimental chemical action would take place on cotton, flax, or wool. Medium asbestos and cotton cloths are used as smoke screens where cinders are an objection. In a few types of air-filtration installations a coarse cotton sheeting is used to take out the heaviest dust particles as the air enters.

As strainers on the ends of flumes in power-house work coarse open-mesh cotton or woolen cloths are used. They are usually called "flume bags" and are used secondarily to wire mesh which prevents the large pieces of substances getting in the pipes. Cotton strainer cloths are used sometimes in the pipes leading to water filters. They are used in canning establishments for the straining of fruit and vegetable juices and somewhat in factories making soups, sauces, relishes, etc. In cider mills a heavier, more open, and thicker cotton cloth is used for the extraction of the apple juice. It is generally a two- to five-ply yarn, loosely woven fabric, resembling a tire fabric in many ways with the exception of the tightness of the weave. This type of cloth is also used in the preliminary straining of other fruit juices.

The filtering of liquid chemicals is done by many kinds of woolen, cotton, linen and asbestos cloth. Some paint makers use a cotton filter cloth also in their manufacturing processes.

In the oil industry cotton filter cloths are used extensively. Crude oil, kerosene, gasoline, benzine, naphtha, linseed oil, cottonseed oil, in fact all kinds of oil, are generally filtered or "pressed" in the making. The cloths range from thin sheeting to heavy duck or multiple-ply hair cloth. When the oil is quite fluid, cotton sheetings and twills are used, and as the viscosity increases the heaviness and thickness of the filtering cloth increase. So next, heavier, thick twills are used, more on the order of a denim, then light duck, army duck and finally the very thick and many-ply cloths where the liquid is forced through by great pressure. These fabrics are of cotton, horse and other hairs. For the heaviest work where they have tremendous strain and pressure, a camel's-hair three- or four-ply cloth is used. These latter types are called "press cloths." In general they are stretched between flanges in a pipe and the oil or liquid forced or "pressed" through them by great pressure, necessitating great strength.

In the case of garbage or sewage reduction the cloths used are of ply yarns, very open and plain weave. Asbestos cloth is used here to great advantage, as it can be cleansed easily by subjecting to fire.

LAMINATED CLOTH

One of the principal uses of laminated cloth is for polishing. Practically always cotton cloth is used, osnaburgs, sheetings and in some cases light duck. Woolen cloth is used in glass polishing to some extent. Laminated cotton-cloth buffers are built up to any desired thickness, stitched, die-cut in circular form and occasionally stitched again spirally. A center of metal or wood is inserted and the polishing wheel is ready for service. This type of polishing wheel is used for polishing leathers, artificial leathers, woods, metals and various kinds of composition materials. It is sometimes used in hat cleaning.

Laminated cotton sheeting impregnated with composition materials of various kinds has been used also in

certain types of universal joints. In the textile industry laminated numbered cotton duck stitched, riveted, or both, is used to some extent on looms in the form of lug straps, check straps and pickers. Fine sheeting and light duck laminated and impregnated with composition materials are used for the making of gears. The blank is built up and the gears are cut the same as if of iron, steel or rawhide. Laminated cotton sheeting alternated with a cheap, light woolen flannel is used at times for making pads on which great pressure is brought and where pressed felt would spread and cause an uneven surface. Laminated cloths are used for packing as noted under that heading.

PACKING

Cotton and asbestos cloths, plain and laminated, are used extensively for mechanical packing, in gaskets and in washers of various kinds. The cotton cloth is generally impregnated with composition materials of various kinds and cut in the desired shapes necessary. Asbestos cloth is used both plain and impregnated in the same manner as cotton cloth. It is used for the most part in places where there is great heat. It has this advantage over cotton-cloth packing, but under a tension the latter is generally better. Impregnated jute cloth is also used at times where a cheap packing is desired and no particular strain or heat is present.

A large amount of cloth packing is consumed by prime movers of various kinds; steam engines and turbines; and gas, kerosene, gasoline, and various kinds of oil engines. It is used generally about any power plant. Pipe joints use impregnated cloth packing of all kinds and the consumption of the material in this way is very large. Light army duck and sometimes a light flat duck are used as the outside covering of asbestos and magnesia pipe coverings.

PADS

Under this heading a closely woven cotton sheeting or sometimes a light twill is used as the covering on inking pads in the printing and engraving industry, particularly on flat-press work. As heretofore described, occasionally a laminated pad made of cotton sheeting and woolen flannel is used on work where there is much pressure against the pad.

Flat ironing machines as used in laundries and homes have a woolen-flannel backing covered with a thick sheeting or light duck as a press pad. This same type of machine somewhat modified is used in tailoring establishments where pressing is done in large quantities.

POLISHING

Cloth is extensively used in polishing all kinds of surfaces. Cotton cloths of various types are laminated, sewed or riveted and then cut in disk form for polishing and buffing. They are used for polishing leather, wood, compositions and metals of various kinds, in the shoe industry and automatic shoe-polishing machines. The jewelry and electroplating trades use this type of polisher to some extent. In some instances cotton webbing is used when a heavy pressure has to be brought to bear.

In the making of lenses and various articles of glass, polishing is done by heavily felted woolen cloths, which cover the polishing wheels. These cloths vary from a thin billiard cloth to a thick heavy melton. Woolen cloths are sometimes used in the finishing of hats.

PUMPING

Flexible cotton hose, plain or treated, is used very generally in pump connections for gases, air and liquids,

especially in industries where a portable pump is necessary. The number of uses is legion and the following are fair examples of its very wide application:

a. For gas work, in the handling of oxygen, nitrogen and most commercial gases.

b. For air use, in the portable vacuum-cleaning outfits on wagons and automobiles, on house, factory, and office cleaners, the connections on compressed-air drills of all kinds, connections on sand-blast cleaning outfits, and on outfits for pumping air to divers.

c. For combination air and liquid pumps, in the connections for various types of atomizers, spraying devices, etc.

d. For liquids, in the connections on water pumps of all kinds; e.g., gasoline motors, fire engines, mine pumps, etc. On spray-painting connections and pumps of that type.

e. For liquids mixed with solids, in the connections for contractors' pumps, dredge pumps, bilge and boat pumps of different kinds, filtration and sewerage pumps, etc.

SIEVES

Cloths of various kinds are used as sieves. The finest is known as silk bolting cloth and is a gauze-type fabric varying from about 20 meshes to the inch up to 200 for the very finest. This is made up to about forty inches in width and is used for sifting flour and any substance which has to be used in very fine powdered form as chalks, paint bases, chemicals, etc. Sieve cloths are made also of linen and cotton in various meshes and weights for not such fine work and where the silk cloth has not the required strength. The weave is practically always plain and the yarns fine.

TREATED CLOTH

Cotton cloth in the form of sheeting, duck, belting, webbing and tape is used extensively as backing for different types of impregnated fabrics, cloth made of other fibers being rarely used. The treated fabrics may be divided in the general classes of rubberized goods, oilcloths, artificial leathers, insulating materials, impregnated laminated cloths, and semi-transparent sheeting. They can best be described in this order.

Rubber-treated cloth is perhaps most used. Tires consume a large amount of sheeting and a special fabric. Belting and webbing are used for conveyors, belts, and straps. Sheeting and duck, plain and laminated, are used for packing gaskets and washers. Sheeting and duck are used for printers' blankets, bolster aprons on machines for removing hair from hides, paper machines, electric separators and various other purposes. Tubular fabrics are used for hose, tubing and sleeve work.

Sheeting and duck made into oilcloth are used in various ways. As a conveyor apron on office duplicating machines, as aprons on paper-mill machinery, as backing on the drums used on a tapestry carpet loom which prints its own filling, and as a conveyor on one of the machines used in fur-hat making. Oilcloth as belting or as webbing is used as a conveyor under certain circumstances where a smooth surface is desired. Its use in photographic-film manufacture and candy making are good examples of this. Oilcloth can in general be used to a great extent in places where a rubber-treated cloth is used.

Artificial leathers are a more recent development and have just started to prove their practicability in indus-

try. So far their use for mechanical purposes is practically nil.

Treated cloths for insulation are described under the heading "Electrical" and laminated treated cloths are discussed under the headings "Polishing and Laminated Cloth."

Semi-transparent treated cloths are used for shades, light filters, and in tracing cloth for mechanical drawings. The cloth used varies from a 4½-yd. cotton sheeting for shades down to a very fine linen for tracing cloth.

WICKS

Cotton webbing and in a few cases soft, thick flat duck are used on machinery for purposes of a wick to convey various kinds of liquids to a certain point. Soft webbing is used in heater appliances for the conveyance of gasoline, kerosene, and various oils to be burned. It is also used in moistening, oiling, gumming and inking machines of various types for conveying the liquid slowly to a certain point or surface.

Industrial Groups

AIRCRAFT

This heading is readily divided into three classes: airplanes, balloons and dirigibles. On airplanes cloth is used in all ways common to the gasoline motor, as described under the heading "Automobile." The wings use cloths of silk, linen or cotton or combinations of these, and the fuselage is sometimes cotton-cloth-covered. Around the gas tank is often found a thick layer of rubber covered with cotton cloth to prevent incendiary bullets from igniting the gasoline. The straps used on the seats are often of cotton webbing in place of leather. The grip of the steering lever is often cloth-covered. Balloons use silk, linen and cotton cloth for the bags. Dirigibles use the same type of cloths for the bags and body coverings.

ARMY

The cartridge carriers for automatic rifles and machine guns are metal or a combination of cotton webbing and canvas. The best types of the latter are woven as a part double cloth separated canvas and part webbing. In this manner is woven on one machine the belt in its entirety with pockets and flat spots as desired. Other carriers are made by stitching two webs or two layers of canvas. The slings and strappings for almost all guns are now cotton webbing in various widths and weights. The straps on gun carriages, wagons, tanks, tractors, etc., are practically all cotton web. Silk cloth is used for powder bags. It is generally a plain-weave, roughly made, silken fabric of coarse yarns spun of silk waste.

AUTOMOBILE

The automobile is a very large user of textile products for mechanical purposes. On the motor, treated-cotton or asbestos-cloth packing, gaskets and washers are used. The fan belt is often either a plain cotton webbing, treated webbing, or an endless belt made by cutting cotton cloth on the bias, building up two to four layers of same and then rubberizing. In this way an endless belt is made which has good wearing qualities. Asbestos wrapping is often used around the exhaust manifold. Practically all water-circulating systems, whether pump or thermostatic, use a rubber-impregnated cotton hose.

Asbestos cloth has been used as a facing for clutches.

Asbestos webbing is used for brake linings, plain, or more often with a wire warp and asbestos filling. Plain, thick cotton webbing is also used as brake linings on the cheaper cars. Foot-pedal grips are usually canvas-backed, rubber-treated cloth. Door straps are of heavy cotton webbing, plain, rubberized, or made into artificial leather.

On a certain type of cheap car a thick, narrow cotton webbing is used in the transmission. Cotton webbing in various widths and weights is used for plain check straps on the axles and for special devices for preventing too rapid recoil of the springs after going over a rough spot in the road.

In the electrical system impregnated silk or cotton cloth and cotton and asbestos tubing are found on the generator, motor, magneto, transformer coil, distributor and wires. A treated cotton sheeting is universally used for covers on the steering connections, magneto distributor, springs, etc. In the making of wheels, particularly a certain type of truck wheel, cotton canvas or duck is used. It is placed as a cushion and fitting device between the spokes and the felloe.

The automobile tire consumes a tremendous amount of cotton cloth annually. Plain tire fabric, cord fabric, breaker-strip cloth, and lining are so well known as to need no mention in this paper. Blow-out patches of a rubberized cotton fabric and tire-tread covers, used mostly in Europe, are usually a cotton-canvas backing reinforced in various ways. In the manufacture of tires a cotton sheeting is used in the mold.

BAKERIES

The majority of cloth consumed is heavy duck, principally "00" weight. It is used as conveyor aprons in the ovens, mixers, conveyors and wrappers in the most modern up-to-date bakeries. Some webbing is used the same way. Heavy sheets of asbestos cloth act as heat protectors in the ovens. When flour or other ingredients in the making of cake have to be finely sifted, a very fine cotton sheeting or silk bolting cloth is used.

CANDY FACTORIES

The same kind of cloths are used in this work as are used in bakeries, with the exception that some of the conveyor belting is of oilcloth, in order to have a smooth surface easily cleansed.

CHEMICAL WORK

Cloths of silk, cotton, linen, wool and asbestos are used in different ways in this industry. They are used principally for sieves and filters. Most of them are of fine, hard-twisted yarns, plain woven goods of various degrees of closeness, though twill weaves and double-cloth fabrics are occasionally used. Cotton goods are used in the greatest quantity and the others about in even proportions.

ELECTRICAL

In this industry cloth is used primarily for insulation work and generally impregnated with a composition material of some kind which is a non-conductor of electricity. For fine-wire insulation and very fine machine work silk tapes and cloth are used. As the sizes increase in each case the tendency is to use cotton tapes or sheeting. Abroad, linen tapes and sheeting are used somewhat, but their use in this country is not general on account of the cost and cotton can be substituted. On cable work cotton and asbestos tubing are also used.

Asbestos webbing is used in the making of large generators.

In the telephone industry the uses of cloth are similar to those already mentioned; one particular webbing, however, is of interest as it is not believed such a web is used in any way comparable to it. A 1½-in. web of wire warp of about forty ends is made with a heavy silk filling to insulate the warp. Diagonally at short intervals across the filling there are open spaces left, leaving the warp bare so that connections can be made. This web is used in switchboard work on board connections.

ENGRAVING

Fine cotton sheeting is used in this industry to cover the inking pads on certain types of engraving machinery. The backing of the engraving press itself is usually a woolen cloth. It is a very fine, closely woven, and closely sheared woolen, very much on the order of a billiard cloth.

FARM MACHINERY

Army and numbered duck, cotton webbing and belting, packing cloths and hose, plain or treated, are used in farm machinery in varying amounts. They are used on tractors, tractor plows, ditch diggers, harvesters, threshing machines and pump connections of all kinds.

HOUSEHOLD MACHINERY

Vacuum cleaners use treated cloth, usually cotton, as air and refuse bags and in certain types narrow cotton webbing is used as a drive belt. The hose connections are rubberized cotton hose. Some washing machines are partly cotton-cloth-lined to prevent splinters getting into the clothes. Narrow cotton webbing is used for driving belts. In certain kinds of carpet sweepers a rubberized narrow webbing is used as bands or rims to drive the brush rolls. Some mechanical mops use loosely bound laminated cotton cloth, generally a low-grade sheeting or osnaburg. On mechanical ironers cloths are used in the same way as in the laundry industry.

MUSICAL INDUSTRY

Both cotton and woolen cloths are used in the manufacture of pianos, inasmuch as felt will not cover every purpose. These are used in the actions and in the keyboards. In piano players cotton webbing also is used for belts and treated cotton cloth in the bellows. In organs cotton strapping is used, treated cotton cloth for bellows and, in case of mechanically driven organs, cotton belting for drive belts. Motor driven music boxes use webbing for belts.

On a few of the best-made phonographs a woolen cloth is placed on top of the metal plate holding the record while being played. This replaces pressed felt. The cloth used for this is very much like a thick, coarse billiard cloth. Heavy cotton sheeting or light twills, drills or flannel are used in the manufacture of the record itself.

LAUNDRY MACHINERY

Cotton or woolen cloth is used quite extensively on this machinery. The principal place, perhaps, is on the rolls of a cylinder ironing machine. These rolls are of metal. First is wound a cotton sheeting; next, many layers of what is termed laundry flannel until a good cushion backing is formed. This flannel is a heavy, straight or broken twill, all-woolen blanket. It is of a coarse wool and heavily napped to get the maximum

cushion effect. On top of this flannel is wound a covering of light duck, usually about a No. 12.

On flat press ironers, resembling an old ironing board, two or three layers of the woolen flannel are used, covered by a couple of layers of cotton sheeting. On the starching machines a very open-mesh cotton cloth is used as a conveyor apron. It is made of about eight-three's yarn counting about eight to twelve warp threads and picks to the inch. On other machinery where conveyor aprons are needed, duck is used but heavier than on the ironing machine. In general the duck is a No. 4, 5, or 6. Woolen strainer aprons or cotton sheets are used to some extent to prevent the cloths from touching the inside of the extractors. These are any old cloths available. In the washing machines or kiers where family "wet wash" is cleansed, open mesh bags are used to hold the cloths, in order to keep each lot separate as they turn over in the machine.

OFFICE MACHINERY

The equipment of most business offices includes typewriters and adding and bookkeeping machines. These all require an inked ribbon for their operation and here a fine textile product is used. It is a cotton cloth made of very fine combed yarns, plain weave and generally from 80 to 100 counts each way. It is split lengthwise, gummed at the edges, inked and wound on small spools ready for use. On the stenotype machines there are also ribbons of this character.

On some adding machines, bookkeeping machines and dictaphones there are belts for driving them by electric motors and these are in most cases fine, narrow cotton webbing. Cotton sheeting and flannel are used in the manufacture of the record for the dictaphone. On duplicator machines of various types the conveyor apron used is a cotton-back oilcloth.

PAPER INDUSTRY

This industry is one of the largest users of textile products, and is entirely dependent on them, as contrasted to other industries where the textile product may be only an aid in producing results. The fabrics used are made of wool or cotton and are called woolen or cotton "felts," as the case may be. A pressed felt was originally used for the purpose and the name has remained, although the product has changed to a woven piece of goods. Woolen "jackets" are also used. These are tubular woven cloths, for shrinking on steel rolls hereinafter described.

The first machine in the paper industry on which a fabric is used is the pulp machine. A thick, open-mesh, plain-weave, heavy, endless woolen fabric takes the stock from a tub and deposits it in layer form on a cylinder from which it is afterward cut in the form of sheets.

On paper-making machines, as the paper stock comes from a revolving wire screen, it is deposited on an endless woven "felt" and by this "felt" is carried through iron press rolls on which is shrunk the heavy woolen "jacket." In this manner the water is squeezed through the "felt" and the thin film of stock or partly formed paper is left on the top of the moving cloth. It is carried through numerous pairs of jacketed rolls and by thicker and finer "felts" and finally is formed paper.

The jackets are tubular two- to five-ply woolen cloths, very closely woven, and felted very hard. They are fulled down to a size less than the roll circumference, and sheared closely; then wet, stretched and placed on the roll. When dry they are so tight they are practically a part of the roll and form an excellent cushion.

The woolen felts mentioned above on which the paper is formed vary from a light, thin, open, well-napped blanket to a close, soft, thick cloth much on the order of a very heavy overcoating. They vary in degrees of openness, thickness, nap, etc., according to the conditions under which run. Double-cloth woolen "felts" having the back cloth a flat, smooth, hard-felted surface and the face cloth of hard yarns are used as "marking felts," to make a special design on the paper after it has left the regular forming felt. "Carrier felts" of coarse, heavy woolen yarns, heavily fulled, are also used at times to convey the paper from one set of rolls to another.

With the paper formed but wet, it is delivered to an endless cotton "felt," which carries it around many steam-heated cylinders until dry. The cotton drier "felt" is a very thick heavy duck. It is usually a three- to eight-ply cloth, each ply averaging as heavy as No. 4 duck. The weight, thickness and yarns used depend on the conditions under which it is run.

Heavy cotton webbing or doubled duck, impregnated with rubber, is used as a guard on each side of the wire screen which delivers the stock to the "felt." This cotton rubber-covered strip is called "deckle strap." Apron conveyors used between the wire screen and first woolen "felt" are made from cotton cloth or duck either rubberized or made into oilcloth.

RAILROAD WORK

Cotton hose, usually treated, is employed for practically all airbrake connections on cars of all types. Also in steam and water connections for cars, round-houses, stations and shops. Some parts of signaling systems use cotton webbing of different widths. On the individual electric car-lighting systems the generator is often driven by a rubberized cotton belt. Webbing in general is used as slings, straps, etc., in railroad-shop work. In steam packing for locomotives cloth is used in general as on a stationary engine. On electric locomotives insulating cloth is used as described under the head of electrical work.

PRINTING

In the printing of textiles, whether silks, linens, cottons, woolens or carpets, cloths are used in three ways. The cylinder which operates against the printing roll is first wound with a linen or linen and woolen lapping. The linen lapping gives a backing to the roll and is used on account of its strength. It is a plain-weave, tightly woven fabric. When the linen and woolen lapping is used, the warp is linen and the filling wool. This gives the requisite strength and more cushion. Stretched around this cylinder to another roll is an endless belt, a sort of woolen jacket, which being next to the cylinder lapping gives the cloth being printed a cushion to work against. This woolen belt is a two- or three-ply, very close, heavily felted cloth, woven endless usually to get a smooth no-lap effect. Under certain conditions of printing a part cotton or a rubberized cotton cloth is used in place of a woolen. In printing filling yarn on a tapestry carpet loom of a certain type a cotton-backed oilcloth is used on the drum. The third place where a cloth is used in this kind of printing is for a leader to carry the cloth to be printed into the machine. It is called the "backgrey" and is a heavy, closely woven cotton sheeting. No matter how many cylinders or printing rolls are used the principle is practically the same.

Narrow fabrics such as ribbons, tapes, fancy straps, suspender and other webbing are printed in practically

the same manner. This same method is also used in printing wallpaper. In rotary printing presses for printing newspapers, magazines, and other big work the principle is the same, the difference being in the method of application. This is likewise so in rotary engraving work, the cloths in general being the same.

When flat printing or engraving is done, however, a cotton-sheeting-covered pad, a heavily felted light woolen, or a laminated cotton cloth and flannel backing are used. When inking is done by pad the covering is cotton sheeting.

TEXTILES

In the manufacture of textiles, cotton, woolen, jute, camel's-hair, linen and asbestos cloths are used. These are so familiar to every engineer in the textile industry that no descriptions of them are necessary; therefore a tabulation only is given in order to have them in proper form. Cotton is used most extensively, approximately 80 per cent of the poundage being of that fiber:

a. Belting. (Cotton or camel's hair, plain or treated):

Main drives
Machine drives
Within machine drives
Narrow conveyors

b. Card Clothing. (Linen, cotton and wool):

Backing for various types of card clothing

c. Clearer, Slasher and Roller Cloths. (Wool and cotton):
Cotton, woolen and worsted work

d. Cotton Duck:

1. Aprons for:

Automatic feeds	Driers	Openers
Blamire feeds	Dusters	Pickers
Camel's-back feeds	Fiber softeners	Scouring machines
Carbonizers	Fur depositors	Take-up rolls
Conveyors	Gill boxes	
Crosser formers	Loom beams	

2. Machine leaders for:

Back filling	Drying	Shearing
Brushing	Felt hardening	Singeing
Calendering	Ironing	Sprinkling
Crabbing	Pressing	Starching
Dewing	Sanding	Water mangling

e. Jackets (Woolen):

Fulling-mill rolls
Gig rolls

f. Jute Cloth:

Aprons on take-up rolls Leader on felt hardeners
Aprons on loom beams

g. Laminated Cloth. (Cotton):

Check straps	Lug straps
Gears	Pickers
Harness straps	

h. Printing. (Cotton, linen and wool):

See general head "Printing"

i. Sheets. (Cotton or wool):

Extractor linings Fulling-mill linings

j. Steaming Blankets:

Wool

k. Tapes and Webbing. (Cotton and asbestos):

Apperly feed bands	Harness straps	Slubbers
Can drier leaders	Mules	Spinning frames
Condensers	Machine belts	Spoolers
Doublers	Reducers	Twisters
Finishers	Roving frames	Winders

SHIPBUILDING

The building of ships consumes much cloth in a mechanical way, not to mention the tons of duck used non-mechanically. It is used as cotton and asbestos packing in engines, turbines and pumps, pipes and pipe covering. Flexible cotton hose is used with certain types of ship pumps and it is also used for dredging sleeves for certain types of dredge pumps. Heavy cotton webbing is being gradually introduced to take the place of ropes where a flat surface is preferable to a round one; this is

particularly advantageous for ship cranes in loading and unloading light cargo.

SHOE INDUSTRY

Wide cotton numbered duck is used on the shoe machines which form the box toes and heels of ordinary shoes. It is used as a forming agent for the parts of the shoe mentioned. Light 12 to 16-oz. duck is also used as backers or formers on other machines. Laminated cotton cloth in the form of buffer wheels is used for polishing.

ASBESTOS

Asbestos cloth is such an unusual product, so unlike any other cloth, that it is advisable to take it up separately. The two main fundamental differences in its use are, first, its heat- and flame-resisting qualities; and second, its neutrality to the actions of acids and alkalis. For these two reasons it can be used in places where no other fabric can. The cloth is usually of heavy yarns and a plain weave, varying in closeness of mesh and thickness as the purpose requires.

The great bulk of this cloth goes into steam packing. It is invaluable in this respect. In this is included gaskets and cut washers. The next largest amount goes into brake linings of all kinds, principally automobile. These may be entirely asbestos or wire warp with asbestos filling. Clutch facings come next in volume.

Filter cloths of various degrees of openness and thickness are used, mostly in chemical plants. Wire backings may be used in this work. This type of filter cloth is also used in making such gases as oxygen and hydrogen, and in such plants where refuse or sewage has to be disposed of. The cloth is easily cleaned by subjecting to fire.

In the electrical industry asbestos cloth is used mostly in webbing or tape form in the manufacture of armatures, etc., and greatly in wire and cable manufacture. Tubing of this material is used also in cable manufacture and gives excellent protection.

For fire doors, heat screens, and curtains a heavy fabric is used, either plain or with a wire warp. Theater curtains are of this type. Iron and steel mills use this cloth around furnaces, etc. Light asbestos cloth is used to wrap asbestos or magnesia packing, but in general heavy cotton sheeting or light duck is best for this purpose.

The making of asbestos board, wall board, linings, shingles, etc., is practically dependent on a textile product, an endless woolen blanket a form of papermaker's felt. The sheet of asbestos is formed on this woolen blanket or felt, the stock being carried through press rolls and finally delivered in a formed but moist sheet to driers. This blanket is made of heavy woolen yarns about one-quarter to one-eighth run, twisted two, three or four strands together. It is a plain weave cloth, about six warps threads and six picks fullled heavily and lightly napped on one side to enable a new felt to easily start the stock. As to the exact workings of this endless woolen blanket or felt, see the paragraphs on "Paper Industry," the principle being the same.

It will be found that in what has gone before there are a number of repetitions due to the unavoidable use of conflicting headings. The author by no means considers that every mechanical use is covered by the paper, but he does feel that it gives an idea of the tremendous use of cloth for mechanical uses and its importance in machine design, construction and operation.

Practical Jokers Among Workmen

BY CHESLA C. SHERLOCK

THE practical joker is a pest only too well known to employers in general. He is found wherever men are gathered together in numbers, whether in shop, factory or office. He is of the type who has abundant faith in his own superintelligence and he does not believe in letting his talents lie dormant.

The sad thing about practical joking is that sooner or later it ends in injury to the victim of the prank; often it ends in death, and the employer is then faced with a very serious situation. Is he, as the employer of the victim, liable for damages to the dependents, or liable for compensation under the workmen's compensation acts? This is only one problem arising out of such horseplay among workmen.

A joke for a joke's sake may be commended and may have a real part in speeding up production and promoting good feeling among the workmen, but practical joking does not belong to this classification of harmless pastime. It has its inception in a deliberate desire to "hurt" someone—the fun of the incident supposedly resting in the subsequent behavior of the victim. It is a deliberate, malicious, mean attempt to trifle with the person or welfare of another, and as a "joke" can appeal only to those having bullying tendencies.

JOKER A SOURCE OF POTENTIAL DAMAGES

Employers ought to be aroused against this practice among workmen, for it is not only to their interest to manifest an efficient organization, but it is to their interest in a financial way to stop these losses of industrial wastage by prohibiting practical joking and horseplay with a firm hand. The employee who indulges in it should be promptly discharged. He may be a valuable man, but he is a constant source of potential danger if his tendency in this direction is allowed free hand.

Employers may be surprised to learn that hundreds of cases growing out of practical joking have found their way to the attention of the courts. Employers have lost thousands of dollars in damages and compensation in paying injured workmen and their dependents for the "jokes" which other employees have perpetrated upon the hapless victim. And the perpetrators of the jokes have gone through life saddened and burdened with the memory of the grim ending of their thoughtless pranks.

TYPICAL EXAMPLES OF PRACTICAL JOKES

In a certain shop the employees had been having considerable "fun" at the expense of a new man who was extremely sensitive and ticklish. One evening just before quitting time, this new employee was carrying a heavy case of material down stairs to the floor below. At the top of the stairs, sitting on the banister reading a newspaper, was another employee, one who had been bullying the new man for several days. Just as the new man started down stairs under his heavy load the other workman quietly folded up his paper and tickled the other fellow in the ribs with it. This caused the new workman to lose his footing and he fell the full length of the stairs, his burden crashing down upon him.

The instances where workmen feel that they have to "initiate" a new workman before he can become a full-fledged member of the organization are legion. The law reports are full of stories where these practical jokers

have worked substantial harm upon the unsuspecting victim.

In one factory it was the custom to require a new workman to look into a box and gaze upon the "Queen of Sheba." When he was intently studying the picture within, a nice shot of flour was released. One day, the workman whose duty it was to load the magazine of this near-infernal machine, mistook lime for flour. When the new fellow gazed into the box his eyes and face were filled with lime. Within three months he was totally blind, and he suffered intense agony.

In a machine shop a workman laid a dynamite cap on the anvil of a new man. Not noticing it, the new workman proceeded with his work and in a few minutes his hammer struck the cap, causing an explosion which deprived him of a thumb and forefinger, as well as causing pieces of metal to be embedded in his chest and forearm.

MACHINERY CATCHES VICTIM OF SKYLARKER

Two men were scuffling near moving machinery in another case. One gave the other a slight shove, causing him to lose his balance. Instinctively, he put out his hand in the direction of the nearby machine. His arm was caught in the belting and was torn from the socket in the twinkling of an eye.

In a factory where female workers were employed one worker dropped a piece of material on the floor. When she leaned over to pick it up a companion worker next to her gave her a shove. Her hair came in contact with the belting and the unfortunate woman was jerked out of her seat and carried to the shafting overhead. By the time the machinery was stopped the scalp had been torn out and the poor woman was disfigured for life. This was a fair sample of a "good-natured" practical joke.

The habit of workmen striking at each other, even in play, should not be tolerated for one moment by the serious-minded employer. Even though they are away from the machinery and there is apparently no immediate danger from a little byplay, it should not be permitted. An example of what may happen is shown in such a case where two workmen passed each other in a factory passageway. One made a swipe at the other, as if to punch his nose. The victim ducked, lost his balance, his feet flew out from under him and he struck his head on the concrete floor. A fractured skull was the result. The first workman testified that all he intended was to brush off the fellow's hat.

LIABILITY OF EMPLOYER FOR INJURY RESULTING FROM "PRACTICAL" JOKING

No employer who is familiar with the law on the subject will tolerate horseplay and practical joking on his premises. He cannot afford to do so, even though he may himself "see no harm" in idle fun. But when the appeal strikes at his financial responsibility, he sees the thing in its grim reality.

Under the common law the employer was not liable for any injury that might occur to a workman in his employ as a result of horseplay, if the one playing the prank was outside the scope of his employment at the time. The courts were very lenient toward employers under the common law régime and it was seldom indeed that a workman succeeded in recovering damages. He had to prove that the one playing the prank causing his injury was within the scope of his employment at the time he did it, and that was an extremely difficult

and sometimes impossible thing for the workman to prove. But, at that, employers did have to pay damages and they often paid them in large sums. When they did pay, they paid whatever the whim of a jury might award to the injured workman or his dependents.

EMPLOYER NOW MORE GENERALLY LIABLE

Now we are operating largely under the compensation system of adjustment of differences between employees and employers. And the rule is different from the common law rule. The common law rule has been completely abrogated and if the victim of the joke was at work within the scope of *his* employment then the employer is liable to him for the injuries received, regardless of the manner in which such injuries arose.

In the vast majority of cases, then, at the present time (in all but six states) the employer is liable for injuries received through horseplay and must foot the bill. Not only that, but there is a moral obligation resting on the employer to protect his workmen from such avoidable injury. And if the employer doesn't fulfill this moral obligation the law will penalize him when the workman is injured.

Therefore, as was said before, it is to the employer's financial benefit that he see to it that all horseplay is forbidden in his establishment, and if an employee persists in playing his practical jokes that he be told to find another field for his activities.

Synopsis of Recent Chemical & Metallurgical Literature

The Why of Aging Clay.—H. SPURRIER, in the February *Journal* of the American Ceramic Society, found in a series of experiments that the evolution of CO_2 continued for over thirty-four days after pugging, and, like the change of plasticity, proceeded more rapidly between 80 and 90 deg. F. than below 60 deg. He also found that the effect of replacing water by non-aqueous liquids was to inhibit the development of plasticity altogether, and that the effect of a dilute solution of H_2O_2 was to produce a pronounced increase of viscosity and also to stimulate the growth of filaments, algæ, with the consequent evolution of both CO and CO_2 . It seems possible, therefore, that the change of plasticity of clays with time is due in some way to the growth of such algæ. This theory would explain all the effects.

In studying the new chemical measure of the plasticity of clays the ratio of the amounts of Al_2O_3 and SiO_2 dissolved by caustic potash was found for three clays tested to decrease rapidly with diminishing plasticity and therefore might well be used as a quantitative measure of plasticity. The practical potter of experience distinguishes readily between sticky and plastic clays by the feel. The above procedure also does this and the result can fortunately be expressed in figures.

Ancient and Modern Methods of Glass Manufacture.—The February, 1921, issue of the *Journal* of the American Ceramic Society contained an original paper on this subject by H. L. DIXON, who has actively participated in the development of scientific methods used in various branches of the glass industry for over forty years. The manufacture of glass-house refractories in early times, the earlier types of furnaces, direct-fired and pot, are briefly described, together with the expansion of the glass-house refractories business.

In the early '70s all window glass and green and amber bottle glass were made in open pot furnaces of the primitive direct-fired type. The regenerative furnace was not

introduced in the United States until 1867. The regenerative pot furnaces are now extensively used with raw producer gas, clean producer gas and natural gas, and have been so improved that greater economy of fuel is obtained as well as largely increased production. These furnaces are built from 14- to 20-pot capacity, the pots being of such dimensions as to contain from 3,000 to 4,000 lb. of glass, the melts being made in about twenty-four hours after filling. The first tank furnace was introduced in the United States about 1880.

The glass industry has migrated with the discovery of natural gas. The first use of natural gas in a glass furnace was at the works of the Bradford Window Glass Co., Bradford, Pa., in 1883. In 1885 the discovery of natural gas in Ohio moved the glass industry West. Later Indiana enjoyed a further development. Still later the industry moved into Kansas and when these fields became exhausted to Oklahoma and Texas. There are few who realize the extent of the migration or evolution in the glass business. In Pittsburgh and the Ohio River districts a great many of the old-established glass-manufacturing companies have actually gone out of business, largely due to the unusual competition of cheap natural gas and the methods employed by newly created manufacturing institutions unfamiliar with the glass trade.

The Manufacture and Treatment of Glass Melting Pots.—W. K. BROWNLEE and A. S. GORTON are the authors of a paper on the manufacture and treatment of glass melting pots published in the February *Journal* of the American Ceramic Society which deals with the raw materials used and methods of grinding and mixing the raw clay and grog, and the way in which glass pots are built and dried.

At present only one grade of pot is made, but the difficulty of getting a pot suitable for all kinds of glass suggests the desirability of making special grades of pots for use with specified kinds of glass. After describing the process in some detail, the authors conclude by emphasizing the point that the technical treatment of pots in the glass plant be intrusted to specially trained men.

The furnace man for obvious reasons should not have this responsibility, and the foremen and the manager, while they have a deeper appreciation of technical matters, are very busy with other questions pertaining to production. Neither should the burden be placed on the chemist, who has all he can do to see to the purity of raw materials and to adjust the glass for color, etc. This duty may be safely intrusted to a young man who has been adequately trained in ceramics and physical chemistry. When more glass manufacturers see the justness of this procedure and employ such men in their plants, real teamwork between the pot factory and the glass factory will be possible and certain troubles which have afflicted the industry for years will disappear to a great extent.

Physical Properties of Materials.—During the past few years the Bureau of Standards has received numerous requests for information regarding the physical properties of materials, principally ferrous and non-ferrous metals and alloys. Some time ago the compilation of most of the available data on this subject was undertaken. The tables which were compiled as a result of this work were issued to a limited number of Government establishments in mimeographed form. As they seemed to fill a very real need, it was deemed advisable to issue them in the form of a Bureau publication, and Circular 101 is the outcome of this work. The circular aims to present in readily accessible form the best available data on the strength and related properties of materials. Among those treated are iron, carbon steel, alloy steels, wire and wire rope, semi-steel, aluminum, copper, miscellaneous metals and other alloys, rope, rubber, leather and wood. The tensile strength, proportional limit, percentage elongation in 2 in., percentage reduction of area, Brinell and scleroscope hardness corresponding to a certain composition, density, and method of preparation are shown in most cases for the metals and alloys. In addition, figures are given in many instances for the compressive and shearing strengths, moduli of rupture, and Erichsen values. The circular also includes definitions of the properties treated and references to sources.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Viscose.—In a cyclic process for the manufacture of artificial threads, films, etc., from viscose, a solution of the latter is prepared with caustic soda obtained electrolytically, the hydrogen and chlorine from the electrolytic cell are united, as for example in an explosion motor, to form hydrochloric acid which with the addition of sodium chloride if necessary constitutes the precipitating bath, and the sodium chloride regenerated during the precipitation is returned to the electrolytic cell. (Br. Pat. 153,444; R. MULLER, Eilenburg, Saxony. Jan. 19, 1921.)

Solder for Enamelware.—In tinning and soldering porcelain enamelware, the solder is applied to the glazed surface of the enamel or to both the enamel and any exposed iron portion, by the use of a steel brush or other steel tool without the aid of a soldering iron or flux. The surface is cleaned and brightened and the vessel then heated over a gas-ring, etc. Solder is then applied by the steel tool, etc., until the surface is tinned and more solder then applied. The solder may consist of 30 per cent of tin, 10 per cent of zinc and 60 per cent of lead. According to the provisional specification, the solder may consist of 75 per cent of tin, 15 per cent of zinc and 10 per cent of lead. (Br. Pat. 153,445; W. B. JOHNSON, Tavistock, Devonshire. Jan. 19, 1921.)

Testing Milk and Cream.—In the process of making butter, the proportion of fat in the milk or diluted cream is estimated with the aid of a solution acting as a solvent for the casein, and containing a considerable amount of potassium sodium tartrate—for instance 150 to 250 g. per liter—and a quantity of alkali corresponding with 105 to 135 g. of sodium hydroxide per liter; 9.7 volumes of milk are mixed with 3.4 volumes of this solution and 0.6 to 62 volumes of isobutyl alcohol, heated to 60 to 70 deg. C., and the quantity of fat read off on the butyrometer glass. A modified solution for use with undiluted cream contains 70 to 135 g. of potassium sodium tartrate and 50 to 70 g. of sodium hydroxide per liter; and the proportions to be taken are 5 volumes of cream, 6.5 volumes of this solution, and 0.6 volumes of isobutyl alcohol. (Br. Pat. 153,446; H. M. HÖYBERG, Copenhagen. Jan. 19, 1921.)

Facilitating Chemical Reactions by Radiations.—The reaction between a gas and another substance is facilitated by subjecting the gas to the action of ultra-violet, Lenard, Becquerel or Röntgen rays and then bringing it into contact with a metallic surface, or by directing the gas on to a metallic surface which is itself subjected to the action of

ultraviolet or other rays. By subjection to the action of these rays, the gas is stated to emit cathode rays whose vibrations are amplified by contact with a metallic surface. Two forms of apparatus are described, corresponding to the alternative methods of activating the gas, such as hydrogen, oxygen or nitrogen. One form, Fig. 1, comprises

a mercury vapor lamp *a* enclosed in a vacuum jacket *b*, a quartz coil *c* through which the gas is passed, a tank *e* for the reacting liquid or the solution of the reacting solid, a bell-jar *f* containing a metallic plate *g*, and a tube *d* for conveying the activated gas into contact with the metallic surface *g* suspended in the reacting liquid or the solution of the reacting solids. The other form of apparatus, Fig. 2, consists of a vacuum bulb *t* provided with an internal electrode *l* and an external electrode *m* surrounding the bulb, the whole being fitted within a closed vessel *n* having inlet and outlet tubes *o* and *p* for the liquid and inlet and outlet tubes *u* and *s* for the gas. In this case the gas, on issuing from the tube *u*, rises through the reacting liquid or the solution of the reacting solid and forms a jacket round the lower part of the vacuum bulb *t*, through which an alternating discharge is taking place. The applications of this process are as follows: The hydrogenation of unsaturated fatty acids or their glycerides, of unsaturated hydrocarbons, of quinine to hydroquinine or of *p*-cresol to methylcyclohexanol; the reduction of fatty alcohols to hydrocarbons, of fatty oxacids to fatty acids, of aliphatic aldehydes to alcohols, of oxaldehydes to aldehydes, of nitriles to amines, of cinnamic acid to hydrocinnamic acid, of nitrobenzene to azoxybenzene, azobenzene, hydrazobenzene and aniline, of nitrobenzene to phenylhydroxylamine; and the syntheses of ammonia and hydrazine. (Br. Pat. 154,213, not yet accepted; E. STATINEANU, Cressy-Onex, near Geneva, Switzerland. Jan. 26, 1921.)

Ammonium Sulphate.—To remove mother liquor from wet sulphate of ammonia, the crystals are placed on a perforated plate *G* within a vessel *A* provided with a cover *D*, and dry steam or steam and air is blown in from the top of pipe by *F* in order to drive the liquid out by a pipe *J* to the saturator *L* or to the tank *K*. Ammonia may be introduced at any stage to neutralize remaining acid. The vessel *A*, which may be steam-jacketed and made of acid-resisting material, is mounted on trunnions *B* to allow of the dried crystals being tipped out into the storage chamber *M*.

(Br. Pat. 154,328; N. WILTON, London, Jan. 26, 1921.)

Hydrocarbon Cement.—Pitch, tar, or other substance consisting mainly of aromatic hydrocarbons, and having a specific gravity of not less than 1.1, is heated to 120 to 180 deg. C., and a powdered inorganic sulphate is stirred in, to produce a cement for general building, road-making, etc., purposes. The sulphates may be hydrated or anhydrous, chemically prepared or as found in nature, for example gypsum, anhydrite, alunite, barytes. The amount of sulphate added may vary between one and four volumes to one volume of tar, etc. The powdered sulphate is added gradually with stirring and the stirring is continued until foaming ceases. In a modification, the tar, etc., and sulphate are placed in a vessel and heated under pressure. The cement is applied at the temperature above stated. The material may also be used as a binder for sand, gravel, broken stone, sawdust or the like. A list of applications is given in the specification. (Br. Pat. 154,152, not yet accepted; W. S. BARRIE and L. CHADWICK, Townsville, Queensland, Australia. Jan. 26, 1921.)

Synthetic Tanning Agents.—An aromatic hydroxy compound or an alkali salt thereof, an aldehyde and an acid sulphite are condensed together in solution at ordinary pressures and at temperatures up to 100 deg. C. The phenol used may be a mixture and may be in the form of a solution of its alkali salt as obtained technically. According to examples, commercial phenol or carbolic liquor is condensed with formaldehyde or acetaldehyde, and sodium bisulphite. The products are suitable for tanning agents, with or without addition of other tanning agents or a metallic salt. (Br. Pat. 154,153, not yet accepted—see also Br. Pat. 154,162, not yet accepted—CHEMISCHE FABRIKEN WORMS, AKT. GES., Frankfurt-on-Main, Germany. Jan. 26, 1921.)

American Engineering Council Opposes Trade Commission Section of Patent Office Bill

The American Engineering Council of the Federated American Engineering Societies will seek at the opening of the special session of Congress to have the Nolan Patent Office bill passed. Failure of the measure in the last session is attributed to the presence of the Federal Trade Commission section, which Edwin J. Prindle of New York, chairman of the American Engineering Council's patents committee, in a report to L. W. Wallace, executive secretary of the Council, asserts should not be enacted into law in any form even as a separate bill. The committee report states its belief that this is a dangerous measure in itself and will open up a most unfortunate activity for the Government.

"The bill for the imperatively necessary relief of the Patent Office, after passing the House of Representatives with satisfactory provisions for the Patent Office, failed to pass the Senate at the session just closed, solely because of the presence in it of an unrelated section known as the Federal Trade Commission section," says the report.

"The former opposition in the Senate to the Patent Office relief and that which forced the unacceptable reductions in salaries and numbers of examiners and clerks (which the conference committee was persuaded to set aside) is largely and seemingly almost wholly overcome. But the opponents in the Senate to the Federal Trade Commission section are determined and have expressed an intention to prevent the Patent Office from getting the desired relief unless the section is removed from the bill.

"More than preventing the Patent Office relief, however, the section is believed to be a dangerous measure in itself. It provides that the Federal Trade Commission may receive assignments of and administer inventions and patents from governmental employees and is an entering wedge for further legislation to empower the Trade Commission to receive patents from non-governmental inventors or owners.

"An exclusive license would have to be granted, at least for a few years, to induce any one to undertake the almost always necessary development expense, and the Trade Commission would surely be charged with favoritism in granting such a license. In order to protect its licenses the Trade Commission would have to sue infringers, a most unfortunate activity for the Government. The industries would close their doors to the Government employees, fearing to disclose to them their secrets or unpatented inventions, and research by the industries would be discouraged for fear that Government employees, using Government facilities, might reach the result first and patent it.

"The Trade Commission, owning a large body of patents, in case one of its patents was found to be infringed during or at the close of a frequently very expensive development by private interests, would be able to dictate in the license the price at which the article which was the object of the development could be sold, or to dictate other similar conditions, thus depriving the development of much of its value; and could even require the licensee, as a condition for granting the needed license, practically to destroy some of its unrelated patents, as by licensing the trade generally when it would prefer to retain the monopoly for itself.

"The foregoing and other objections would result in making patents less desirable to own or to purchase, and consequently would decrease the incentive to produce inventions.

"The proposed section is unnecessary for the protection of Government employees, since they now have all the rights which non-governmental employees have to patent inventions and to sell them. It is therefore believed that the Federal Trade Commission section should not be enacted into law in any form, even as a separate bill."

Government Needs Chemists and Other Laboratory Workers

The United States Civil Service Commission states that there are openings in the Government service for associate chemists at \$2,500 to \$3,600 a year, assistant chemists at \$1,800 to \$2,500 a year and junior chemists at \$1,200 to \$1,800 a year. Appointees at an annual compensation of \$2,500 or less will also be allowed the increase of \$20 a month granted by Congress. It is stated that the openings offer opportunities for those who are qualified in the various specializations of chemistry.

The commission also announces that the Ordnance Department at Large, War Department, needs catalytical chemists at \$3,000 to \$4,000 a year, assistant catalytical chemists at \$2,000 to \$3,000 a year and junior catalytical chemists at \$1,600 to \$2,000 a year. The increase of \$20 a month is allowed for these positions also when the basic pay is not more than \$2,500 a year.

There is also need in a number of Government establishments for laboratory assistants, laboratory aids and laboratory apprentices of various kinds, requiring training in chemistry, physics, ceramics, textile technology, paper technology, civil, mechanical and electrical engineering, etc.

Full information and application blanks may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or by calling upon the secretary of the United States Civil Service Board at the post office or custom house in any city.

Steam Economy in Drying Paper

The March meeting of the Connecticut Valley Section of the Technical Association of the Pulp and Paper Industry was held in Holyoke March 21. Pursuant to the Section's policy in dealing thoroughly with the problem of paper drying at the meetings this year, the speaker was Mr. Fulton of the Fulton Engineering Co. of Middletown, Ohio, who discussed the process of controlled drying by the use of the equipment manufactured by his company.

The drying problem as a whole has suddenly become of great importance to paper makers, particularly those in New England, because of the price of coal and the necessity for cutting costs of manufacture. Mr. Fulton showed how it was possible to get greatly increased production without the use of additional steam for drying. As many mills average 2 lb. of steam to dry 1 lb. of paper, such results are well worth while, particularly when machines that have required live steam for drying are able by the use of an efficient separating system to substitute exhaust steam. The driers on a paper machine make ideal condensers, and when the proper valves are in place to insure the removal of air and exhaust steam used with efficient traps and a closed system, so that nearly all the condensate is recovered free of dissolved gases, the cost of operating the power plant may be often materially reduced.

Laundering Problems

The Laundry Owners Association of the Hampden County district of Massachusetts held an open meeting in Holyoke March 25. Miss Wakefield of the Mellon Institute of Industrial Research was the principal speaker. Her address was illustrated with slides showing in detail some of the trials of the laundryman, particularly in connection with faulty or cheap textiles which may be so woven as to conceal defects which soon become apparent when the goods are laundered. She also described in detail the work of the National Laundryman's Association fellowship at Mellon Institute.

Progress in Survey of Industrial Waste

The committee of the American Engineering Council on "Elimination of Waste in Industry" is making rapid progress in its field surveys. Ten basic industries have been selected for the investigation, and at least six plants in each industry will be covered. These industries are: Bituminous coal, transportation, building trades, men's clothing, paper, printing, metal trades, textiles, shoes and rubber. Information is being obtained systematically through a questionnaire that has been prepared for the field workers, and the selection of plants has been so made as to give a geographical cross-section of each industry. In addition to the national inquiry into the ten basic industries a regional survey will be made of industries in the city of Worcester, Mass. The results of each survey will be embodied in reports of the field directors for each industry as follows: First, a full engineering report; second, a 3,000 to 5,000-word digest for the technical press; third, a 1,200 to 1,500-word digest for the daily press, and fourth, 500 to 600-word articles for the daily press. It is hoped and expected that these reports will be completed and ready for distribution within the next sixty to ninety days.

Program of Atlantic City Meeting of Electrochemical Society

Unusual interest is being manifested in the forthcoming meeting of the American Electrochemical Society at Atlantic City, April 21 to 23. In addition to an unusually good technical program, the essential features of which are presented herewith, special attention has been given to social events that will make the convention attractive. Acheson Smith and Carl Schluederberg have announced an old-fashioned reunion of the "Us Old Trappers Association" for the purpose of demonstrating their prowess with the rifle and pistol in one of the shooting galleries on the Boardwalk. A trapping exhibition is also announced, but details are suppressed. Prizes will be provided for all grades of marksmanship. All of the foregoing is arranged in addition to the golf tournament for the championship of the Electrochemical Society.

Headquarters will be at the Chalfonte Hotel and registration will begin at 6 p.m., Wednesday, April 20. Ladies are especially welcome and will be entertained by a committee which is arranging some interesting events. A feature of the technical program is a symposium on corrosion. Details of the program follow:

THURSDAY, APRIL 21

9:30 a.m. Session for Reading and Discussion of Papers.

Symposium on Corrosion

William H. Walker: Introduction to Symposium on Corrosion of Iron and Steel.

W. D. Richardson: The Gap Between Theory and Practice in the Production of Corrosion-Resisting Iron and Steel.

A. S. Cushman and G. W. Coggeshall: Anomalies Encountered in a Study of Immersion Tests of Iron and Steel.

J. M. Aupperle and D. M. Strickland: Observations on the Corrosion of Iron and Steel.

F. N. Speller: Practical Means of Preventing Corrosion of Iron and Steel Where Not Exposed Directly to the Atmosphere.

D. M. Buck: Some Observations on the Mechanism of the Increased Corrosion Resistance of Steel and Iron Due to Small Copper Contents.

O. P. Watts and H. C. Knapp: The Effect of Copper and Silver Salts on the Corrosion of Iron by Acids.

E. A. Richardson and L. T. Richardson: The Corrosion of Old Iron.

O. W. Storey: The Corrosion of Steel Ranges.

B. G. Worth: Unusual Boiler Tube Corrosion by Carbon Dioxide.

2 p.m.

Sports and recreations, contests, etc.

6 p.m.

The board of directors will hold a dinner-meeting, at the Chalfonte Hotel, for transaction of usual business.

8 p.m.

Lecture in the auditorium of the Chalfonte Hotel (across North Carolina Ave. from the hotel). R. B. Moore, of the Bureau of Mines, Washington, D. C., will lecture on

"Helium: Its Production, Properties and Uses." After the lecture informal discussion and conversazione. Award of prizes for the sport contests held Thursday.

FRIDAY, APRIL 22

9:30 a.m. Annual Business Meeting of the Society

Report of the board of directors.

Announcement of annual election.

Reports of various committees.

Presidential address of the retiring president, W. S. Landis.

Reading and Discussion of Papers

Symposium on Corrosion (continued)

H. A. Gardner: Metal Protective Paints.

O. P. Watts: Principles of Alloying to Resist Corrosion.

H. S. Rawdon: Some Types of Non-Ferrous Corrosion.

E. R. Shepard: Electrolytic Corrosion of Lead by Continuous and Periodic Currents.

Other Papers

O. H. Eschholz: Phenomena of Arc Welding.

H. W. Gillett: Electric Furnaces for Non-Ferrous Metals.

Carl Hering: Electrodynamical Forces in Electric Furnaces.

E. F. Northrup: Recent Progress in High Frequency Induction Heating.

W. G. Mylius: The Regulation of Electric Steel Arc Furnaces Using Movable Electrodes.

2 p.m.

Sports and recreations, contests, etc.

8 p.m.

Exhibition of moving pictures of industrial plants in the auditorium of the Chalfonte Hotel:

The Chuquicamata, Chile, Copper Extraction Plant of the Chile Exploration Co.

The Muscle Shoals Nitrate Plant of the American Cyanamid Co.

Dancing after the picture show as soon as the seats can be removed from the auditorium.

Award of prizes for the sport contests held on Friday.

SATURDAY, APRIL 23

9:30 a.m. Reading and Discussion of Papers

T. R. Briggs and W. J. Bartlett: Adsorption of Arsenious Oxide by Metastannic Acid.

L. Kahlenberg and W. J. Trautmann: Reduction by Means of Silicon.

Theodore W. Case: A Photo-Electric Effect in Audion Bulbs of the Oxide-Coated Filament Type.

S. E. Sheppard: Electrochemical Aspects of Photographic Development.

A. S. McDaniel, L. Schneider and A. Ballard: The Electrolytic Manufacture of Para-aminophenol.

W. A. Noyes: Some Aspects of Electrolytic Iron.

William Blum: Use of Fluorides in Solutions for Nickel Deposition.

C. P. Madsen: Ductile Electrolytic Nickel.

C. W. Hazelett: A New High Capacity Storage Battery.

C. W. Marsh: Marsh Electrolytic Cell Batteries for Chlorine, Caustic Soda and Hydrogen.

Government Smokeless Powder Sold

The Director of Sales, War Department, announces the sale, through the agency of the Ordnance Salvage Board, of 28,000,000 lb. smokeless powder to the Bethlehem Chemical Co. of Washington, D. C.

The price to be paid by the purchaser is $\frac{1}{2}$ c. per lb., "as is, where is." By the terms of this sale the United States is to receive 60 per cent of the net amount received by the purchaser in the event that any of this material is resold or reworked and resold for use as smokeless powder.

General Fries Gets Recess Appointment

General Amos A. Fries, head of the Chemical Warfare Service, has been given a recess appointment by President Harding to assume the rank of Brigadier General. General Fries was one of a large number of Army officers whose promotions were not confirmed at the recent session of Congress. The reasons were political and in no way reflected upon the nominations for positions other than those commonly classed as patronage. In order to reserve for the incoming Administration as many as possible of the patronage positions practically no confirmations were made during the last session.

Personnel Research Federation

Under the auspices of the National Research Council and Engineering Foundation, the Personnel Research Federation has been organized to bring about interchange of research information among the numerous organizations which are engaged in personnel research. It is reported to the new federation by the Bureau of Labor Statistics, of the Department of Labor, that there are 250 such organizations in the United States. The Personnel Research Federation will collect research information, will encourage research through individuals and organizations and will co-ordinate research activities. This federation includes in its membership scientific, engineering, labor, management and educational bodies.

Temporary officers have been elected as follows: Chairman, Robert M. Yerkes, representing National Research Council; vice-chairman, Samuel Gompers, representing American Federation of Labor; treasurer, Robert W. Bruere, representing Bureau of Industrial Research; secretary, Alfred D. Flinn, representing Engineering Foundation; acting director, Beardsley Ruml, assistant to the president of Carnegie Corporation of New York.

The aims of the new organization are:

Increased efficiency of all the personnel elements of industry—employer, manager, worker—and improved safety, health, comfort and relationships.

The immediate purposes of the Personnel Research Federation will be:

To learn what organizations are studying one or more problems relating to personnel and the scope of their endeavors.

To determine whether these endeavors can be harmonized, duplication minimized, neglected phases of the problems considered, and advanced work undertaken.

Present Status of Nitrogen Fixation in Germany

Calcium cyanamide factories engaged in the production of nitrogen fertilizers by process of fixation of atmospheric nitrogen were in operation in Germany before the war, but during the war these plants were extensively enlarged and are now in process of completion. The total output of these plants when properly supplied with coal is estimated at 600,000 tons, with a nitrogen content of 120,000 tons. Several plants representing this production, together with the possible output of each, are as follows:

	Tons
Mitteldeutsche Stickstoffwerke A. G. Plesteritz.....	175,000
Oberschlesische Stickstoffwerke A. G. Chorzow.....	150,000
Aktiengesellschaft für Stickstoffduenger, Knapsack, Gross Kayna	140,000
Bayerische Stickstoffwerke A. G., Trostberg and Margarethenberg	75,000
Lonzawerke, Waldshut	60,000
Total	600,000

At the present time these plants are producing approximately 500,000 tons of calcium cyanamide, with a nitrogen content of 100,000 tons.

Prior to the war the production of nitrogen fertilizers by coke and gas industries reached a figure of 580,000 tons, with a nitrogen content of 116,000 tons. However, the coal shortage has militated against the maintenance of production at these figures.

The Badische Anilin und Sodafabrik is the only concern producing nitrogen fertilizers by the Haber-Bosch process. Its first factory for this purpose was constructed at Oppau. Operations began at this plant in 1913. A second plant, known as the Ammonia Works of Merseburg, which is twice the size of the Oppau plant, was later erected, and has been in operation since 1917. When properly supplied with raw material the annual output of nitrogen in both of these plants is 300,000 tons, corresponding to 1,500,000 tons of sulphate of ammonia.

Before the war Germany's annual agricultural requirements of nitrogen fertilizers were 210,000 tons of nitrogen, of which 100,000 tons was in the form of nitrate of soda and nitrate of lime (imported), 100,000 tons in the form of sulphate of ammonia of home production and 10,000 tons in the form of calcium cyanamide, likewise of home production. At the outbreak of the war there was only 40,000

tons of nitrate of soda within the country, which was immediately taken for the manufacture of ammunition. The total production of nitrogen fertilizers by the plants now existing and those in process of construction will approximate 500,000 tons of nitrogen, equal to more than twice the amount required for agricultural purposes before the war.

In spite of their high cost nitrogen fertilizers are in great demand in Germany today. A quantity of sulphate of ammonia containing 1 kilo of nitrogen cost 1.35 marks in 1913, as against 12 marks in 1920. At the same time 100 kilos of ammonia fertilizer with 20 per cent nitrogen cost 27 marks in 1913, as against 240 marks in 1920.

Legislators Visit Edgewood Arsenal

A number of members of the Committees on Military Affairs of the Senate and of the House visited Edgewood Arsenal March 31 as the guests of General Fries. General Fries has been trying for some time to induce members of Congress, who are charged with duties pertaining to the Chemical Warfare Service, to get a first-hand idea of the work which is being conducted by the service. Despite the proximity of Edgewood to Washington this is the first time it has been possible to get any considerable number of legislators together for such a trip.

Radium Production

The Standard Chemical Co., of Pittsburgh, reports a production of 18 g. of radium sulphate for 1920. Most of it was used for medical purposes, although some went into the manufacture of luminous dials for watches.

Treatment at the mines of 500 tons of Colorado carnotite yields 125 tons of concentrate, which is shipped to Pittsburgh. Preliminary refining reduces this amount to 0.5 ton and approximately 1 g. of radium results from further refining. The product is put up in milligrams and sealed by the Bureau of Standards. It sells for \$120,000 a gram.

A.S.M.E. to Discuss Steam Equipment Codes

Nineteen Power Test Codes, constituting what their framers style "a national common law" in the field of power plant testing are being framed by 125 leading engineers, scientists and educators under the auspices of the American Society of Mechanical Engineers, and will be discussed at the Chicago meeting May 23 to 26.

The codes, when completed, will affect a wide range of industrial enterprises, large and small. They will provide courses of procedure by which everything from an electrical superstation to a boiler fed pump shall be tested to see if they comply with the terms of purchase or if they are operating at the desired efficiency.

The discussion at the Chicago meeting will relate to the adoption of the Power Test Code containing rules for conducting tests of steam engines and evaporating apparatus, and will be open to the public. Manufacturers, members of engineering societies and technical and scientific men from many cities are planning to give their views on the question of adoption of these codes prior to their final sanction by the Society.

The third of the nineteen to be completed is described by the committee as intended primarily for the testing of apparatus heated by steam, such as vacuum pans, or single- and multiple-effect evaporators. The principal use for such evaporators is in the manufacture of alkali, salt, sugar, condensed milk, extracts from chemicals, and similar processes.

The committee in charge of the preparation of this code is headed by E. N. Trump of the Solvay Process Co., Syracuse, N. Y. The other members of the committee are B. N. Bump and L. C. Rogers of the Solvay Process Co.; E. A. Newhall, designing and construction engineer, of Philadelphia, and H. L. Parr, assistant professor of mechanical engineering, Columbia University.

Three codes have already been completed: one, in the nature of a preliminary set of rules, is entitled "General Instructions." This code was prepared by a committee under the chairmanship of William H. Kavanaugh, professor of

experimental engineering in the University of Pennsylvania. His associates on the committee are C. J. Bacon of E. I. du Pont de Nemours & Co., Wilmington, Del.; Prof. Arthur M. Greene, Jr., of Rensselaer Polytechnic Institute, Troy, N. Y.; and C. F. Hirshfeld of the Detroit Edison Co., Detroit, Mich.

The individual committee in charge of a test code first submits a preliminary draft to the secretary of the main committee. This draft is edited and returned to members of the individual committee by the secretary, to whom an edited revision is returned approved. The draft is then set in type and proofs are distributed to a selected list of from one to two hundred engineers for criticism, after which the individual committee submits the revised code to the main committee. The main committee then returns the code to the individual committee for further revision, and then submits the revised draft of the code to the Council, the governing body of the Society, and asks permission to print and present it to the Society. When the Council, consisting of thirty members representing cities East and West, gives leave to print, the code appears in *Mechanical Engineering*, the official journal of the Society. The next step is the submission of the code to the Society at a regular meeting, where it is either approved and adopted or is returned for further revision.

This Chicago public presentation and discussion of three test codes will be one event in an elaborate program of social, economic and technical discussions in which men of nationwide prominence will figure.

Personal

WILLIAM P. ALLEN, director of the service department at the works of E. I. du Pont de Nemours & Co., Wilmington, Del., has been appointed assistant treasurer of the company. At one time Mr. Allen was employed as a research chemist at the company's plant at Repauno, N. J., and later was located in the chemical department at the Wilmington works. He will be succeeded in the service department by William B. Foster, who has heretofore been assistant chief engineer.

WILLIAM V. ANDERSON, who was formerly with the Aetna Explosives Co. as superintendent of acid plants, has gone into consulting and construction service for acid manufacture at Garvanza, Cal.

JAMES W. BOILEAU, metallurgist and consulting engineer, El Paso, Tex., was in Chicago recently on business.

R. V. BROWN, superintendent of the Sherwin-Williams Co. Chicago plant, spoke before the Chicago Chemists Club March 22 on "The Application of Chemistry to Paint and Varnish."

Dr. HAROLD HIBBERT, assistant professor of chemistry in Yale University, has been promoted to an associate professorship of applied chemistry, and assigned to the Graduate School and the Sheffield Scientific School.

Dr. F. GOWLAND HOPKINS, professor of biochemistry at the University of Cambridge, delivered the ninth Harvey Society lecture at the New York Academy of Medicine Saturday evening, April 2. His subject was "The Chemical Dynamics of Muscle."

CHARLES S. MADDOCK, JR., of the Thomas Maddock's Sons Co., Trenton, N. J., manufacturer of chinaware, gave an interesting address on the subject of bone china before the members of the local Rotary Club March 24.

Prof. A. A. MICHELSON, head of the department of physics at the University of Chicago, has been appointed exchange professor at the University of Paris. His course of lectures will be on the general subject of "Physics" and will be given in the French language.

Dr. ERNEST FOX NICHOLS, director of scientific research at the Nela Park laboratory of the National Electric Lamp Association, Cleveland, Ohio, has been elected president of

the Massachusetts Institute of Technology, to take office on July 1. Dr. Nichols was formerly professor of physics at Yale University and also held the presidency of Dartmouth College.

Dr. ROBERT F. RUTTAN, head of the department of chemistry, McGill University, has been appointed to succeed Dr. Duncan G. MacCallum as administrative chairman of the Advisory Council for Scientific and Industrial Research in Canada.

ALEXANDER SILVERMAN gave a timely illustrated address on the subject "The Contributions of Chemistry to the Comfort of Man," at the Carnegie Lecture Hall, Pittsburgh, on March 24.

CLINTON K. TEXTOD has severed his connection with the Mead Research Co. to accept a position as chemical engineer with the Northwest Paper Co., Cloquet, Minn., in connection with proposed developments which are not yet announced.

CHARLES S. WITHERELL, formerly metallurgical engineer for the Chile Exploration Co., announces that he is open for engagement in a consulting capacity on metallurgical plants and processes. His new office is at 150 Nassau St., New York City.

Obituary

C. E. HAVILAND, of the Haviland China Co., died on March 30 at Limoges, France. Mr. Haviland was of American descent, the founder of the firm, Theodore Haviland, having left the United States because of the difficulty in obtaining local porcelain artisans. The American origin of the firm served it well in 1905 during a labor riot. Mr. Haviland flew the Stars and Stripes over his plant when the mob became menacing and being a United States consular representative, the area of the works became legally American territory, as a consequence of which the mob was overawed.

THOMAS LYNTON BRIGGS, of the General Chemical Co., died Sunday morning, April 3, of heart disease, at his home, 188 Central Ave., Flushing, L. I. Mr. Briggs was born on Dec. 27, 1857, in London, and received his doctor's degree under Fresenius. He came to America in 1886 and joined the G. C. Co. at Laurel Hill twenty-one years ago on the first of this month. He is survived by his wife and children, Prof. Thomas R. Briggs of Cornell and Miss Adelaide Briggs.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, April 4, 1921.

A gradual improvement has been noted in the demand for production in the first-hand market for heavy chemicals. March has been decidedly better from the manufacturer's viewpoint than any month since the present period of depression. The country's industrial wheels are making slow but steady progress and with this development more conservative buying can be expected. General conditions have shown a larger vein of optimism and leading factors are sure of a brighter future. Profits have been comparatively small and prices have been on the decline in the face of foreign competition, but the business which is being conducted now seems of a steadier character and limited to a conservative trade between makers and consumers. Speculators have gradually dwindled from the market owing to the continued uncertainty of the price situation and while there still are a few left their territory is confined to only a few items of comparatively small lots that have no mate-

rial bearing on the industry. The unsettled political outlook in Germany has been reflected in the potash market as well as in other chemicals which recently have been offered for import from leading German interests. In spite of continued adversities arising every now and then in several directions, the domestic situation seems very promising and a gradually increasing feeling of confidence is being felt throughout the trade.

With the advent of spring encouraging reports are heard from the paint and building trades. The textile mills are running along in better swing at most points than at any other previous time this year and the present demand from consumers of woollens has kept woolen mills in steady operation. Demand for paper appears to be temporarily satisfactory and the call for chemicals used at paper mills is not as active as noted at the beginning of the year. Soap factories are taking chemicals only for immediate necessities. Shoe factories seem to be doing a very good business and have been in the market for miscellaneous chemicals quite frequently.

Export buying has not been featured by any important activity.

GENERAL CHEMICALS

Among the week's developments were further reports of curtailment of caustic soda output and buyers experienced some difficulty in securing any special brands. Leading producers of caustic seem to be firm in their belief that prices cannot be lowered from 3½c. per lb., basis 60 per cent, works and make a legitimate profit. Soda ash has ruled comparatively steady and buyers experienced great difficulty in obtaining carlots at low figures. Bichromate of soda declined to 7½c. per lb., but closed above this figure when inquiries were noted from exporters for large quantities. Producers were naming 8@8½c. per lb. for the soda and 12@13c. for the potash. Acetate of soda fell to a new low record for the year under an absence of support from consuming trades. Bleaching powder has been offered by prominent sellers, including manufacturers, at new low prices. Muriate of potash sold as low as \$57 per ton, basis 80 per cent, delivered. Carbonate of potash sold down to 7c. per lb. Resale lots of formaldehyde sold as low as 15c. per lb. under second-hand competition. Commercial white powdered arsenic has declined under a quiet inquiry. Red arsenic is also a trifle weaker. Leading producers of cyanide of soda have been able to maintain their regular price of 30c. per lb. and buyers have been willing to pay their price on account of the sterling quality regardless of the low prices named on imported goods. Prussiate of soda has not recovered from its recent slump and trading has been of a very limited nature throughout the week.

Supplies of *glacial acetic acid* in second hands have been pretty well worked off and the recent low priced goods are gradually being taken off the market. One large producer is holding spot goods at \$9.30@\$11 per 100 lb., depending on quantity. Manufacturers of *ammonia alum* have reduced their prices and are now quoting on a basis of 4c. per lb. Imported white granular *sal ammoniac* is to be had on the spot market at 7@7½c. per lb. Domestic producers are still holding their prices well above this level, but are doing no noticeable business. American producers of *barium chloride* are still quoting \$85 per ton, with the imported material quoted on the spot market at \$65@\$70 per ton. Shipment prices on German chloride have been heard as low as \$60. Manufacturers of *bleaching powder* have openly announced a reduction in price to \$2.75 per 100 lb. f.o.b. works, but the trade has refused to come into the market in view of repeated offers from second hands at figures well below this quotation. Prices as low as \$2.40 f.o.b. works have been done by producers for round quantities and offers were heard even lower. The spot market is around 2½c. per lb. Producers of *chlorate of soda* named 10c. per lb. for standard American material. Odd lots of resale stock are reaching the market at 9@9½c. per lb. with occasional lots of imported goods down as low as 8½c. per lb. Moderate trading was noted during the week with small lot business predominating. Prices quoted for *permanganate of potash*, U.S.P., are lower on spot at 35@40c. per lb., although it is under-

stood that offerings of imported material in large lots are well below this figure.

Trading in the coal-tar products market during the past week reflected a shade of improvement and many are prompted to believe that the consuming demand will show favorable developments. Sales in general were confined mostly to small lots and were pretty well scattered. Progress in this industry will no doubt be of a very slow nature, but the next few months will undoubtedly witness a substantial increase in trading as resale stocks become less apparent.

The crude market is fairly active and some increase in the volume of business is noted. Benzene, toluene and solvent naphtha are lower. Resale interests are finding their stocks dwindling and makers generally have been content to hold prices up until all this resale material has been taken up.

Makers of intermediates are finding a very slow demand in the majority of cases, but are doing a gradually increased amount of business with the reopening of fur dye houses and woolen mills.

Refiners of *benzene* are quoting lower prices following a lack of interest from consumers and also due to keen competition in some quarters. The present prices of pure benzene are given as 27c. per gal. in tank cars and 29@32c. per gal. in drums, according to quantity. The 90 per cent grade is quoted on the same basis at 25@28c. per gal. Business has shown some signs of improvement and the reduced prices are believed to be a spur for the consuming element to come into the market. Stocks of *naphthalene* in second hands are being gradually worked off and while it is still possible to pick up an odd lot at 8c. per lb., the market in general is showing a very firm tendency. Makers' prices are being held at 8½@9½c. per lb. for the flake and 9½@10½c. for the balls. Producers of *solvent naphtha* have reduced their quoted prices and now name 25@28c. per gal. in tank cars and drums, according to quantity. *Toluene* prices have also been reduced by makers and it is quoted at 28@31c. per gal. The consuming demand has been very slow of late.

Some *aniline oil* business is being done by producers, as stocks in second hands have failed to come up to specifications. Prices remain more or less uncertain and are subject to shading on firm business. Makers quote 23@28c. per lb., according to seller, while distressed lots are offered freely at 21c. and lower. Manufacturers of *beta naphthol* reported some new export business, but it seems that the spot market is still in control of second hands, who are quoting around 33c. per lb. Makers are holding the prices up around 40@45c. per lb. Business in *para amidophenol* among fur dyers is very active and stocks are moving quite freely. Prices have remained unchanged at former levels with the base quoted at \$1.90 per lb. and the HCl at \$2.10.

VEGETABLE OILS

The market for *castor oil* was inactive and the undertone barely steady despite the recent reduction in prices announced by manufacturers. First hands quote the U.S.P. grade at 9½c. per lb. No. 3 oil was nominal at 8½@8¾c. Prices named for *chinawood oil* both here and at the Coast vary somewhat. There were sellers on the spot at prices ranging from 9@9½c. per lb., while on the Coast prices ranged from 7½@8c. The market for *coconut oil* during the week was rather dull, but prices appeared to be on a fairly steady basis, reflecting firmer ideas on the part of some sellers. *Ceylon style oil* of domestic make was offered at 8½c. per lb., nearby delivery, in sellers' tanks. Barrels was nominal at 9½c. per lb. Producers of *corn oil* quoted the market for crude material unchanged on the basis of 8c. per lb. The market for *palm oil* was quiet and prices were unsettled. Lagos held at 7c. c.i.f. N. Y. for immediate shipment and niger at 6½c.

WAXES

The market for *beeswax* was a quiet affair, but prices closed about unchanged on all varieties. There were no important changes in the *carnauba wax* market. Prices for the lower grades were steady on the basis of 20c. per lb. for the chalky and 18c. for the No. 3 North Country. Quota-

tions for the higher grades were more or less nominal. Spot offerings of *Japan* wax were moderate and with no apparent selling pressure quotations were maintained at 19@20c. per lb. New business in *paraffine* wax came forward rather slowly and with offerings of crude and the lower grades of refined noted on a somewhat liberal scale, prices presented an unsettled appearance. Some operators reported a steadier tone for the higher grades of refined. Producers offered scale wax, 124-126 deg. melting point, for immediate shipment at 2½c. per lb. in carlots. There were sellers of the 130 deg. m.p. refined as low as 5c. per lb.

The Iron and Steel Market

PITTSBURGH, April 1, 1921.

It seems now to have become well established that the iron and steel market is to be uneventful in that it will not for some time exhibit startling changes in degree of activity or in price changes. The whole trade would be gratified if it became possible to repeat market performances of the past, when sharp declines in prices were followed by a "buying movement," as in the fall of 1904, February, 1909, the fall of 1911, and the year 1914. Cutting by independent steel producers of the Steel Corporation or Industrial Board price schedule began approximately two months ago, following the decline late last year of the independent market to the Steel Corporation level. In the first few weeks the declining tendency was sharp, but in the past month there has been but little declining tendency, and in the past week declines have been exceptional. Rather there has been a firming or steadying tendency, noticed chiefly in bars, shapes and plates, which are quotable in carload lots, with desirable specifications, at 2c. for bars and 2.10c. for shapes and plates for two or three weeks past, but with less disposition than formerly to shade these prices for larger lots. This is the logical result of demand being of its present character. The prices mentioned are below those of the Steel Corporation by \$7 a ton on bars and shapes and \$11 on plates. Yet the corporation receives probably as much business as the independents, or more, in fresh orders and in releases against orders previously suspended.

In black sheets 4.75c. can be done as readily on carloads as 4.85c. a week ago, with galvanized similarly at 4.80c. against 5c. In standard steel pipe concessions of 2½ or 5 per cent are more common than a week ago, being possible on less desirable orders than formerly. Many products are so inactive as not to disclose any well defined market price.

DEMAND

The demand for steel products continues to broaden, in point of number of orders or of releases on orders previously suspended, but all the demand is of hand to mouth character, chiefly in carload lots, and representing depletion of stocks rather than an increase in actual consumption. One cannot, thus far at least, observe a tendency for consumption to increase now that spring is here. The manufacture of automobiles is gradually picking up, but the consumption is chiefly of steel already in stock. Whether production of automobiles will continue to increase when it must be with fresh steel remains to be seen.

PIG IRON

The basic pig iron market remains in charge of the steel interests that have stocks of iron, their price being \$23 valley or possibly less, while the merchant furnaces have pegged their price at \$25 and are hoping the stocks will be exhausted in a few months. Bessemer pig iron has been quoted at \$25 valley, against the former nominal quotation of \$27. Foundry iron remains at the \$25 price to which it declined somewhat over a week ago.

Mattie furnace, Girard, Ohio, goes out of blast to-day, while Perry at Erie is going in. The resumption threw a little light on coke market conditions, as a three months' supply was bought at \$4.50 or a shade less. With additional wage reductions effective at some works today it is thought the next sale will be at nearer \$4.25, the test being probably furnished by a purchase to be made for a furnace at Portsmouth, Ohio, which is to blow in and will require Connellsville coke for about six weeks, 500 tons a day, until its byproduct coke plant can be started.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

	Carlots	Less Carlots
Acetic anhydride.....lb.	\$0.12 - \$0.12½	\$0.40 - \$0.45

Lactic, 22 per cent tech.....lb.	4.00 - 4.50	06 - 07
Molybdic, C. P.....lb.	06 - 07	4.50 - 5.00
Muriatic, 20 deg. (see hydrochloric).....lb.	07 - 08	07 - 07½
Nitric, 40 deg.....lb.	07 - 08	08 - 08½
Nitric, 42 deg.....lb.	16 - 17	17 - 17½
Oxalic, crystals.....lb.	17 - 18	18 - 19
Phosphoric, Ortho, 50 per cent solution.....lb.	30 - 32	35 - 40
Picric.....lb.	1.90 - 2.15	1.90 - 2.15
Pyrogallol, resublimed.....lb.	15.00 - 16.00	15.00 - 16.00
Sulphuric, 60 deg., tank cars.....ton	19.00 - 20.00	23.00 - 23.50
Sulphuric, 60 deg., drums.....ton	22.00 - 22.50	23.00 - 23.50
Sulphuric, 66 deg., tank cars.....ton	23.00 - 24.00	23.00 - 23.50
Sulphuric, 66 deg., drums.....ton	25.00 - 26.00	26.50 - 27.00
Sulphuric, 66 deg., carboys.....ton	32.00 - 35.00	40.00 - 45.00
Sulphuric, fuming, 20 per cent (oleum) tank cars.....ton	1.15 - 1.25	1.15 - 1.25
Sulphuric, fuming, 20 per cent (oleum) drums.....ton	48 - 50	48 - 50
Sulphuric, fuming, 20 per cent (oleum) carboys.....ton	36 - 40	36 - 40
Tannic, U. S. P.....lb.	1.30 - 1.40	1.30 - 1.40
Tannic (tech.).....lb.	4.75 - 5.00	4.75 - 5.00
Tartaric, crystals.....lb.	40 - 45	40 - 45
Tungstic, per lb. of WO.....lb.	50 - 54	50 - 54
Alcohol, Ethyl.....gal.	04 - 04½	04 - 04½
Alcohol, Methyl (see methanol).....gal.	05 - 06	06 - 06½
Alcohol, denatured, 188 proof.....gal.	13 - 13½	14 - 14½
Alcohol, denatured, 190 proof.....gal.	02 - 02½	02 - 02½
Alum, ammonia lump.....lb.	03 - 03½	03 - 03½
Alum, potash lump.....lb.	07 - 07½	07 - 07½
Alum, chrome lump.....lb.	30 - 32	33 - 35
Aluminum sulphate, commercial.....lb.	09 - 09½	10 - 11
Aluminum sulphate, iron free.....lb.	08 - 08½	09 - 09½
Aqua ammonia, 26 deg., drums (750 lb.).....lb.	08 - 08½	09 - 09½
Ammonia, anhydrous, cyl. (100-150 lb.).....lb.	2.90 - 3.00	3.10 - 3.20
Ammonium carbonate, powder.....lb.	4.00 - 4.25	4.00 - 4.25
Ammonium chloride, granular (white salamoniac) (nominal).....lb.	3.25 - 3.50	3.25 - 3.50
Ammonium chloride, granular (gray salamoniac).....lb.	08 - 08½	09 - 10
Ammonium nitrate.....lb.	08 - 08½	09 - 10
Ammonium sulphate.....100 lb.	2.90 - 3.00	3.10 - 3.20
Amylacetate.....gal.	4.00 - 4.25	4.00 - 4.25
Amylacetate tech.....gal.	3.25 - 3.50	3.25 - 3.50
Arsenic oxide, (white arsenic) powdered lb.	08 - 08½	09 - 10
Arsenic, sulphide, powdered (red arsenic) lb.	12 - 12½	13 - 14
Barium chloride.....ton	60.00 - 65.00	70.00 - 75.00
Barium dioxide (peroxide).....lb.	19 - 20	21 - 22
Barium nitrate.....lb.	11 - 11½	12 - 12½
Barium sulphate (precip.) (blanc fixe).....lb.	04 - 05	05 - 06
Bleaching powder (see calc. hypochlorite).....lb.	04 - 05	05 - 06
Blue vitriol (see copper sulphate).....lb.	04 - 05	05 - 06
Borax (see sodium borate).....lb.	04 - 05	05 - 06
Brimstone (see sulphur, roll).....lb.	40 - 41	42 - 45
Bromine.....lb.	40 - 41	42 - 45
Calcium acetate.....100 lbs.	1.60 - 2.00	1.60 - 2.00
Calcium carbide.....lb.	04 - 04½	04 - 04½
Calcium chloride, fused, lump.....ton	27.00 - 29.00	30.00 - 32.00
Calcium chloride, granulated.....lb.	01 - 01½	02 - 02½
Calcium hypochlorite (bleach'g powder) 100 lb.	2.40 - 2.60	2.75 - 3.00
Calcium peroxide.....lb.	1.25 - 1.50	1.25 - 1.50
Calcium phosphate, tribasic.....lb.	15 - 16	15 - 16
Camphor.....lb.	65 - 68	65 - 68
Carbon bisulphide.....lb.	07 - 08	08 - 08½
Carbon tetrachloride, drums.....lb.	10 - 10½	11 - 12
Carbonyl chloride (phosgene).....lb.	75 - 1.00	75 - 1.00
Caustic potash (see potassium hydroxide).....lb.	08 - 09	09 - 10
Caustic soda (see sodium hydroxide).....lb.	08 - 09	09 - 10
Chlorine, gas, liquid-cylinders (100 lb.).....lb.	08 - 09	09 - 10
Chloroform.....lb.	38 - 40	38 - 40
Cobalt oxide.....lb.	3.00 - 3.10	3.00 - 3.10
Copperas (see iron sulphate).....lb.	24 - 25	26 - 27
Copper carbonate, green precipitate.....lb.	05 - 05½	06 - 06½
Copper cyanide.....lb.	05 - 05½	06 - 06½
Copper sulphate, crystals.....lb.	05 - 05½	06 - 06½
Cream of tartar (see potassium bitartrate).....lb.	05 - 05½	06 - 06½
Epsom salt (see magnesium sulphate).....lb.	05 - 05½	06 - 06½
Ethyl Acetate Com. 85%.....gal.	90 - 1.00	90 - 1.00
Ethyl Acetate pure (acetic ether 98% to 100%).....gal.	15 - 15½	15 - 15½
Formaldehyde, 40 per cent.....lb.	15 - 15½	15 - 15½
Fusel oil, ref.....gal.	3.50 - 3.75	3.50 - 3.75
Fusel oil, crude.....gal.	2.00 - 2.25	2.00 - 2.25
Glauber's salt (see sodium sulphate).....lb.	18 - 19	18 - 19
Glycerine, C. P. drums extra.....lb.	3.75 - 3.85	3.75 - 3.85
Iodine, resublimed.....lb.	10 - 20	10 - 20
Iron oxide, red.....lb.	1.20 - 1.40	1.20 - 1.40
Iron sulphate (copperas).....100 lb.	1.05 - 1.10	1.20 - 1.40
Lead acetate.....lb.	13 - 14	13 - 14
Lead arsenate, pas e.....lb.	08 - 09	09 - 10
Lead nitrate.....lb.	15 - 20	15 - 20
Litharge.....lb.	08 - 09	09 - 10
Lithium carbonate.....lb.	1.25 - 1.50	1.25 - 1.50
Magnesium carbonate, technical.....lb.	10 - 11	11 - 12
Magnesium sulphate, U. S. P.....100 lb.	2.75 - 3.00	2.75 - 3.00
Magnesium sulphate, technical.....100 lb.	2.25 - 2.50	2.25 - 2.50
Methanol, 95%.....gal.	75 - 77	75 - 77
Methanol, 97%.....gal.	78 - 82	78 - 82
Nickel salt, double.....lb.	13 - 14	13 - 14
Nickel salt, single.....lb.	14 - 14½	14 - 14½
Phosgene (see carbonyl chloride).....lb.	45 - 46	47 - 50
Phosphorus, red.....lb.	35 - 37	35 - 37
Phosphorus, yellow.....lb.	12 - 12½	13 - 14
Potassium bichromate.....lb.	12 - 12½	13 - 14

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar)..... lb.	\$. . . \$. . .	\$0.30 - \$0.35
Potassium bromide, granular..... lb.		.20 - .40
Potassium carbonate, U. S. P..... lb.	.35 - .40	.45 - .50
Potassium carbonate, crude..... lb.	.07 - .08	.09 - .10
Potassium chlorate, crystals..... lb.	.08 - .10	.11 - .15
Potassium cyanide..... lb.		.40 - .45
Potassium hydroxide (caustic potash)..... lb.	.09½ - .10	.10½ - .11½
Potassium muriate..... ton	57.00 - 65.00	
Potassium iodide..... lb.		2.75 - 3.00
Potassium nitrate..... lb.	.09½ - .09½	.10 - .12½
Potassium permanganate..... lb.	.35 - .37	.38 - .40
Potassium prussiate, red..... lb.	.48 - .50	.51 - .53
Potassium prussiate, yellow..... lb.	.26 - .27	.28 - .29
Potassium sulphate (powdered)..... per unit		2.15 - 2.25
Rochelle salts (see sodium potas. tartrate)		
Salammoniac (see ammonium chloride)		
Sal soda (see sodium carbonate)		
Salt cake..... ton		32.00 - 34.00
Silver cyanide..... oz.		1.30 - 1.35
Silver nitrate..... oz.		.38 - .40
Soda ash, light..... 100 lb.	1.95 - 2.10	2.15 - 2.40
Soda ash, dense..... 100 lb.	2.20 - 2.30	2.40 - 2.60
Sodium acetate..... lb.	.05 - .05½	.05½ - .06
Sodium bicarbonate..... 100 lb.	2.50 - 2.60	2.70 - 3.00
Sodium bichromate..... lb.	.07½ - .07½	.07½ - .08
Sodium bisulphate (nitre cake)..... ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphate powdered, U.S.P..... lb.	.05½ - .05½	.06 - .06½
Sodium borate (borax)..... lb.	.06½ - .06½	.07 - .07½
Sodium carbonate (sal soda)..... 100 lb.	1.90 - 2.00	2.25 - 2.50
Sodium chlorate..... lb.	.09 - .09½	.10 - .10½
Sodium cyanide, 96-98 per cent..... lb.	.19 - .20	.21 - .30
Sodium fluoride..... lb.	.12 - .12½	.13 - .14
Sodium hydroxide (caustic soda)..... 100 lb.	3.60 - 3.70	3.80 - 4.00
Sodium hyposulphite..... lb.		.03½ - .04
Sodium nitrate..... 100 lb.	2.60 - . . .	2.70 - . . .
Sodium nitrite..... lb.	.06 - .06½	.06½ - .07
Sodium peroxide, powdered..... lb.	.28 - .29	.30 - .32
Sodium phosphate, dibasic..... lb.	.04½ - .04½	.05 - .05½
Sodium potassium tartrate (Rochelle salts) lb.		.27 - .28
Sodium prussiate, yellow..... lb.	.13 - .13½	.13½ - .14
Sodium silicate, solution (40 deg.)..... lb.	1.25 - 1.35	1.40 - 1.50
Sodium silicate, solution (60 deg.)..... lb.	.03 - .03½	.03½ - .03½
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.75 - 2.00	2.25 - 2.50
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.05½ - .05½	.05½ - .06
Sodium sulphite, crystals..... lb.	.04 - .04½	.04½ - .05
Strontium nitrate, powdered..... lb.	.15 - .15½	.16 - .17
Sulphur chrl. ride, red..... lb.	.07 - .07½	.07½ - .08
Sulphur, crude..... ton	20.00 - 22.00	
Sulphur dioxide, liquid, cylinders..... lb.	.08 - .08½	.09 - .10
Sulphur (sublimed), flour..... 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone)..... 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent..... lb.	.18 - .19	
Tin oxide..... lb.		.40 - .42
Zinc carbonate, precipitate..... lb.	.16 - .18	.19 - .20
Zinc chloride, gran..... lb.	.11 - .11½	.11½ - .12
Zinc cyanide..... lb.	.45 - .49	.50 - .60
Zinc dust..... lb.	.12 - .13	.13½ - .14
Zinc oxide, XX..... lb.	.08½ - .09	.09½ - .10
Zinc sulphate..... lb.	.03½ - .03½	.04 - .05

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude..... lb.	\$1.15 - \$1.25
Alpha-naphthol, refined..... lb.	1.45 - 1.50
Alpha-naphthylamine..... lb.	.38 - .40
Aniline oil, drums extra..... lb.	.20 - .26
Aniline salts..... lb.	.26 - .29
Anthracene, 80% in drums (100 lb.)..... lb.	.75 - 1.00
Benzaldehyde U.S.P..... lb.	1.00 - 1.50
Benzidine, base..... lb.	.90 - 1.00
Benzidine sulphate..... lb.	.75 - .80
Benzoic acid, U.S.P..... lb.	.65 - .70
Benzoate of soda, U.S.P..... lb.	.65 - .70
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.)..... gal.	.25 - .28
Benzyl chloride, 95-97%, refined..... lb.	.28 - .30
Benzyl chloride, tech..... lb.	.25 - .27
Beta-naphthol benzoate..... lb.	3.50 - 4.00
Beta-naphthol, sublimed..... lb.	.70 - .75
Beta-naphthol, tech..... lb.	.33 - .45
Beta-naphthylamine, sublimed..... lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.)..... lb.	.16 - .18
Ortho-cresol, in drums (100 lb.)..... lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums..... gal.	.90 - .95
Cresylic acid, 75-97%, dark, in drums..... gal.	.85 - .90
Cresylic acid, 50%, first quality, drums..... gal.	.55 - .60
Dichlorobenzene..... lb.	.06 - .09
Diethylaniline..... lb.	1.25 - 1.30
Dimethylaniline..... lb.	.50 - .60
Dinitrobenzene..... lb.	.30 - .32
Dinitrochlorobenzene..... lb.	.25 - .30
Dinitronaphthalene..... lb.	.33 - .35
Dinitrophenol..... lb.	.40 - .45
Dinitrotoluene..... lb.	.25 - .27
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.38 - .40
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.30 - 1.50
Meta-phenylenediamine..... lb.	1.20 - 1.25
Monochlorobenzene..... lb.	.14 - .16
Monoethylaniline..... lb.	1.90 - 2.00
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.08 - .08½
Naphthalene, flake..... lb.	.08 - .09½
Naphthalene, balls..... lb.	.09½ - .10
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3.20 - 3.75
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.17 - .20
Ortho-toluidine..... lb.	.25 - .30
Para-amidophenol, base..... lb.	1.90 - 2.00
Para-amidophenol, HCl..... lb.	2.10 - 2.20

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.85 - .90
Para-nitrotoluene..... lb.	.90 - 1.05
Para-phenylenediamine..... lb.	1.90 - 2.00
Para-toluidine..... lb.	1.25 - 1.60
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.11 - .13
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.85 - 2.00
Resorcinol, pure..... lb.	2.30 - 2.50
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.22 - .23
Salicylic acid, U. S. P..... lb.	.24 - .26
Salol..... lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.30 - .35
Tolidine..... lb.	1.35 - 1.45
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.42 - .45
Xylene, pure, in tank cars..... gal.	.45 - . . .
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - . . .

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 - \$0.26
Beeswax, refined, light..... lb.	.27 - .28
Beeswax, white pure..... lb.	.40 - .45
Carnauba, Florida..... lb.	.68 - .70
Carnauba, No. 2, North Country..... lb.	.30 - .32
Carnauba, No. 3, North Country..... lb.	.18 - .19
Japan..... lb.	.19½ - .20
Montan, crude..... lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.03½ - .03½
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.02½ - .03
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 - .04½
Paraffine waxes, refined, 125 m.p..... lb.	.04½ - .05
Paraffine waxes, refined, 128-130 m.p..... lb.	.05 - .06
Paraffine waxes, refined, 133-135 m.p..... lb.	.06 - .06½
Paraffine waxes, refined, 135-137 m.p..... lb.	.06½ - .06½
Stearic acid, single pressed..... lb.	.11 - . . .
Stearic acid, double pressed..... lb.	.11½ - . . .
Stearic acid, triple pressed..... lb.	.12 - .12½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.70
Pine oil, pure, dest. dist..... gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.36
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990..... gal.	.37
Pinewood creosote, ref..... gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl..... 280 lb.	\$4.90 - . . .
Rosin E-I..... 280 lb.	5.15 - . . .
Rosin K-N..... 280 lb.	5.50 - . . .
Rosin W. G.-W. W..... 280 lb.	6.00 - . . .
Wood rosin, bbl..... 280 lb.	6.25 - . . .
Spirits of turpentine..... gal.	.59 - . . .
Wood turpentine, steam dist..... gal.	.57 - . . .
Wood turpentine, dest. dist..... gal.	.56 - . . .
Pine tar pitch, bbl..... 200 lb.	. . . - 7.00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	. . . - 14.50
Retort tar, bbl..... 500 lb.	15.00 - 14.75
Rosin oil, first run..... gal.	.45 - . . .
Rosin oil, second run..... gal.	.48 - . . .
Rosin oil, third run..... gal.	.60 - . . .

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.17 - \$0.18
Upriver coarse..... lb.	.11½ - .12½
Upriver caucho ball..... lb.	.14 - .14½
Plantation—First latex crepe..... lb.	.18½ - . . .
Ribbed smoked sheets..... lb.	.16 - . . .
Brown crepe, thin, clean..... lb.	.18 - . . .
Amber crepe No. 1..... lb.	.20 - . . .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.08½ - \$0.08½
Castor oil, AA, in bbls..... lb.	.09 - .10
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.07 - .07½
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .09½
Cocoonut oil, Cochin grade, in bbls..... lb.	.09 - .10
Corn oil, crude, in bbls..... lb.	.08 - .08½
Cottonseed oil, crude (f. o. b. mill)..... lb.	.04 - .04½
Cottonseed oil, summer yellow..... lb.	.06 - . . .
Cottonseed oil, winter yellow..... lb.	.07 - .07½
Linseed oil, raw, car lots (domestic)..... gal.	.65 - . . .
Linseed oil, raw, tank cars (domestic)..... gal.	.58 - . . .
Linseed oil, in 5-bbl lots (domestic)..... gal.	.68 - .70

Olive oil, commercial.....	gal.	\$1.90	—	\$2.50
Palm, Lagos.....	lb.	.07	—	.07½
Palm, Niger.....	lb.	.06	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.05½	—	.05½
Peanut oil, refined, in bbls.....	lb.	.10½	—	.11
Rapeseed oil, refined in bbls.....	gal.	1.05	—	1.10
Rapeseed oil, blown, in bbls.....	gal.	1.15	—	1.20
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07½	—	.07½
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04½	—	

FISH

Light pressed menhaden.....	gal.	\$0.45	—	\$0.47
Yellow bleached menhaden.....	gal.	.47	—	
White bleached menhaden.....	gal.	.49	—	
Blown menhaden.....	gal.	.84	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	12.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

DECATUR—The Alabama Brick & Tile Co., Scottsboro, Ala., has preliminary plans under way for the erection of a new plant on the Tennessee River, near Decatur, for the manufacture of brick, tile and other burned clay products. W. B. Neher heads the company.

California

GLENDALE—The Tropico Potteries, Inc., recently organized, has taken over the plant of the Pacific Minerals & Chemical Co., Tropico district, for its proposed new works. Plans are under way for a number of extensions and the installation of considerable new equipment, including a continuous tunnel kiln, drying apparatus, etc. The plant will be devoted to the manufacture of architectural terra cotta, faience tile, vitrified clay sewer pipe and other burned clay products. B. M. Wotkyans is president; F. B. Ortman, formerly connected with the Northwestern Terra Cotta Co., Chicago, Ill., is vice-president and general manager.

Idaho

WEISER—Brizenline Bros. is reported to be planning for the construction of a new plant for the manufacture of brick and other burned clay products. A tract of clay lands near the city now owned by the company will be used.

Illinois

CHICAGO—The Imperial Japanning & Enameling Co., 408 West Grand Ave., has awarded a contract to Holton, Seelye & Co., 140 South Dearborn St., for the erection of a new 1-story and basement plant, 48x205 ft., at 1644 West Austin Ave., to cost about \$40,000. William Link is general manager.

CHICAGO—Sewell Clapp Envelopes, Inc., 23 North Desplaines St., manufacturer of paper specialties, will take bids early in May for the erection of its proposed new 1- and 2-story plant, 200x209 ft., at Belmont and Tripp Sts., to cost about \$250,000 with machinery. M. D. Strong is president.

Indiana

HAMMOND—The Moorhead Oil Co. is considering the rebuilding of the portion of its plant destroyed by fire March 21, with loss estimated at about \$200,000.

EVANSVILLE—The Pretty Soap Co., recently organized with a capital of \$100,000, has acquired the former plant of the Melzer Soap Co., and will operate the works for the manufacture of soap, oils and kindred products. The factory will be remodeled and improved. It is planned to inaugurate operations at an early date. The new company is headed by Henry N. Mannheimer and Adolph Decker.

NOBLESVILLE—The American Strawboard Co. has resumed operations at its local plant after a shutdown of about two months, giving employment to approximately 100 men.

Kansas

CHANUTE—The Ash Grove Lime & Portland Cement Co., Grand Avenue Temple Bldg., Kansas City, Mo., will commence construction at once of a new power plant at its works at Chanute, 80x160 ft., to cost about \$100,000.

Kentucky

LOUISVILLE—The Standard Sanitary Mfg. Co., 628 Shipp St., manufacturer of sanitary earthenware products, has awarded a contract to C. A. Koerner, Floyd and Burnett Sts., for the erection of a new 1-story and basement pottery, 75x200 ft., to cost about \$75,000. It will be equipped for the manufacture of sanitary porcelain specialties.

Maryland

BEL AIR—The Maryland Flint & Feldspar Co. has acquired the property of the Husband Flint Products Co., on Deer Creek, Harford County, consisting of about 140 acres of land with mill and other buildings. The new owner will enlarge the works and plans for extensive development. Ground flint and feldspar for the pottery industry will be produced at the plant. The work is estimated to cost about \$150,000. C. L. Gray is president.

BALTIMORE—The Piedmont-Mt. Airy Guano Co., operating a plant at Curtis Bay for the manufacture of fertilizer products, has arranged for a bond issue of \$500,000, the proceeds to be used for extensions, general operations, etc. Edwin W. Levering is president.

BALTIMORE—Fire on March 27 destroyed one of the buildings at the plant of the Excelsior Brick Co., Benson Ave., Violetville. An official estimate of the loss has not been made.

BALTIMORE—The Gwynns Falls Paper Co. is being organized to construct a new plant at Gwynns Falls, near Baltimore, for the manufacture of boxboard and paper products. The company is capitalized at \$600,000, and it is said that the new mill will cost in excess of \$150,000 with machinery. Joseph H. Wallace & Co., 5 Beekman St., New York, are engineers for the project.

Massachusetts

TAUNTON—The Presbrey Stove Lining Co., Weir Village, has plans under way for the rebuilding of its firebrick and refractory plant, recently destroyed by fire, with loss estimated at about \$100,000, including equipment. A total of 20 buildings on the 5-acre site occupied by the plant were destroyed or damaged.

SPRINGFIELD—The United States Envelope Co. is planning for the early occupancy of its new plant, now nearing completion. The factory will be four-story brick, and with machinery will cost about \$400,000. The Casper Ranger Construction Co., Bond St., Holyoke, Mass., is the building contractor.

Michigan

BATTLE CREEK—The American Stamping Co. has taken bids and will soon award the contract for the erection of its proposed new 1- and 2-story plant for the manufacture of stamped metal goods, 110x225 ft. J. C. Llewellyn, 38 South Dearborn St., Chicago, Ill., is architect.

DURAND—The Briggs Co., Lansing, has plans under way for the erection of a new plant at Durand for the manufacture of brick, tile and kindred burned clay products. The company has a 100-acre tract of property here, and will utilize a portion of the site for the new works. It is now operating a similar plant at Grand Ledge, Mich.

New Jersey

EDGEWATER—The Archer Daniels Linseed Co., Minneapolis, Minn., manufacturer of oil products, is taking bids for the erection of its proposed new plant on property recently acquired at Edgewater; it will be 1-story brick.

NEWARK—The Noxon Co., manufacturer of metal polishes and kindred specialties, has purchased the 3-story and basement plant at 66-78 Morris Ave., totaling about 16,000 sq.ft., on site 100x212 ft., for a local works.

TRENTON—The Adamtex Brick Co., 171 Madison Ave., New York, organized recently with a capital of \$1,000,000, is planning for the construction of a new branch plant at Trenton. W. L. Wootan is president, and Newton A. K. Bugbee, vice-president and treasurer.

New York

NEW YORK—The Jespersen Newsprint Corp. has arranged for a stock issue of \$250,000, a large portion of the proceeds

to be used for the establishment of a new paper mill in the vicinity of New York. The plant will have an initial capacity of about 35 tons, and will be operated under a special chemical and mechanical process. Other mills will be constructed at a later date. Fremont W. Spicer, vice-president of the *Fourth Estate*, 232 West Fifty-ninth St., is secretary.

NEW YORK—The American Agricultural Chemical Co., 2 Rector St., has disposed of a bond issue of \$30,000,000, the proceeds to be used in part for proposed expansion and improvements in fertilizer plants. A mortgage on the company's property to an amount of \$36,000,000, to secure the bonds, has been filed. The Vance Guano Works, a subsidiary organization, has plans under way for the erection of a new fertilizer manufacturing plant in the vicinity of Henderson, Ga., to cost about \$500,000 with machinery. It will have a capacity of about 50,000 tons per year.

NEW YORK—The Vacuum Oil Co., 61 B'way, operating refineries at Rochester and Olean, N. Y., and Bayonne, N. J., has arranged for a note issue of \$20,000,000.

North Carolina

HAMLET—The Carolina Pine Products Co. has plans under way for the construction of a new local refinery for the manufacture of pine tar, pine oil, turpentine and kindred products. A list of equipment for installation has been arranged. C. R. Poole is president.

Ohio

YOUNGSTOWN—The benzol plant at the works of the Brier Hill Steel Co. was partly destroyed by fire March 18, with loss estimated at \$25,000.

TIFFIN—The Standard Sanitary Mfg. Co. is completing the installation of new pressing department. The machinery at the former local building is being removed to a new factory.

CANTON—The United Alloy Steel Corp. has been merged with the Berger Mfg. Co. and the United Furnace Co., all of this place, under the first noted name. Plans are under way for the construction of a new open-hearth furnace and finishing mill.

Pennsylvania

PITTSBURGH—The Standard Sanitary Mfg. Co., manufacturer of sanitary earthenware, has purchased property from the Pennsylvania Light, Heat & Power Co., at Margaret St. and Ontario Ave., Northside, to be used in connection with its plant extensions.

READING—The Standard Chemical Works has inaugurated operations at its new local plant for the manufacture of compounds, insecticides and chemical products.

MARCUS HOOK—The Union Petroleum Co., 17 Battery Pl., New York, has acquired property totaling about 200 acres of land, known as the "Reading Farm," located between Marcus Hook and Chester, and is reported to be planning to use the site for the construction of a new oil refining plant.

Quebec

MONTREAL—The Industrial & Educational Publishing Co. is planning for the erection of a new paper mill at St. Ann-de-Bellevue, about 20 miles from Montreal, to be used for the manufacture of high-grade paper products.

Texas

FORT WORTH—The Invincible Oil Corporation, operating a local refinery, with similar plant at Shreveport, La., has arranged for a bond issue of \$3,000,000, the proceeds to be used for expansion, operations, etc. J. B. Shearer is vice-president.

COMMERCE—The Trinity Paper Mills, Dallas, is planning for the construction of a new local paper mill, with initial output of about 50 tons per day. The plant will specialize in the manufacture of writing paper, tissue and blotting paper. It will be operated in conjunction with a new pulp mill, now nearing completion, and which is expected to be ready for service during April; this pulp mill is located at Commerce. George W. Lull is president.

Washington

BLEWETT—The Amalgamated Gold Mines Co. is planning for the erection of a new hydro-electric power plant at its property to cost about \$60,000. C. R. Hesseltine is president.

New Companies

THE LOCKWOOD GLASS CO., 929 Clinton St., Ottawa, Ill., has been incorporated with a capital of \$200,000 to manufacture glassware. The incorporators are H. C. Lockwood, W. I. Hibbs and Lothrop Perkins.

THE AMERICAN PINE PRODUCTS REFINING CO., Salisbury, Md., has been incorporated with a capital of \$250,000 to manufacture refined oils, etc. The incorporators are H. D. Elliott, Salisbury; B. A. Deal, Jr., Nashville, Ga.; and H. F. Hogeboom, Savannah, Ga.

THE GERUS MFG. & CHEMICAL CORP., New York, N. Y., has been incorporated under Delaware laws with a capital of \$1,500,000 to manufacture chemicals and chemical by-products. The company is represented by Arthur W. Britton, 34 Cedar St.

THE FUEL OIL CORP., Brooklyn, N. Y., has been incorporated with a capital of \$2,000,000 to manufacture petroleum products. The incorporators are I. Gordon, C. A. Kursel and J. J. Dodson, 291 Adams St.

THE FEDERAL LEATHER CO., Salem, Mass., has been incorporated with a capital of \$60,000 to manufacture leather products. The incorporators are Arthur G. Frothingham, A. G. Frothingham, Sr., and H. W. Nolan, Salem.

THE FRANKLIN DRUG & CHEMICAL CO., 227 West Austin Ave., Chicago, Ill., has been incorporated with a capital of \$25,000 to manufacture chemicals and affiliated products. The incorporators are Benjamin and John Segal.

THE CROSS LABORATORIES, INC., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture rubber specialties. The incorporators are S. H. Sears, F. H. Butehorn and J. L. Watson, 37 Wall St.

MARCUS WARD, INC., Boston, Mass., has been incorporated with a capital of 234,600 to manufacture paper products. The incorporators are Alexander W. Murray, Marcus E. Mahon and Ray Henry, Boston.

THE OLEANDER OIL CO., Richmond Hill, L. I., has been incorporated with a capital of \$75,000 to manufacture oil products. The incorporators are D. F. Sullivan, J. E. McPoland and W. M. Duffy, Richmond Hill.

THE PACIFIC RUBBER ACE CO., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture rubber goods. The incorporators are S. L. Ploeser, B. F. Jacobs and H. W. Hanson, all of Los Angeles.

THE YOUTH-GLAND CHEMICAL LABORATORIES, INC., 56 East Randolph St., Chicago, Ill., has been incorporated with a capital of \$30,000 to manufacture chemicals and chemical byproducts. The incorporators are Walter Haenichen, Leonard Breckwoldt and Lewis J. Ruskin.

THE NICHOLSON SUPPLY CORP., Fredericksburg, Va., has been incorporated with a capital of \$30,000 to manufacture mineral and vegetable oils. The incorporators are George B. Nicholson, Arthur D. Nicholson, both of Pittsburgh, Pa.; and C. O'Connor Goolrick, Fredericksburg.

THE RICHARDSON SPECIALTIES CO., Napoleon, Mich., has been incorporated with a capital of \$25,000 to manufacture chemical products. The incorporators are Joseph M. Richardson, Napoleon; Charles W. Chapman and Adam L. Gloor, 439 Henry St., Detroit, Mich.

THE AMERICAN PAPETERIE CO., Boston, Mass., has been incorporated with a capital of \$400,000 to manufacture paper goods. The incorporators are Alexander W. Murray and Marcus E. Mahon, 43 Leon St. The company will be affiliated with Marcus Ward, Inc., Boston.

THE AMYLAC CO., 208 North Wabash Ave., Chicago, Ill., has been incorporated with a capital of \$10,000 to manufacture glues, pastes, etc. The incorporators are Paul Kreismann, Rae and Austin H. Woods.

THE NIAGARA PETROLEUM CO., Lockport, N. Y., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are Roy J. Chase, Louis L. Patterson and Alfred B. Leibold, Lockport.

THE WHITE CROSS CHEMICAL CO., Lynn, Mass., has filed notice of organization to manufacture chemical compounds. The company is headed by G. A. Liljgren, 40 Elmwood Ave.

THE KNOXVILLE FERTILIZER CO., Knoxville, Tenn., has been incorporated with a capital of \$500,000 to manufacture fer-

tilizers. The incorporators are H. L. Dullin, James W. Dean and S. B. Carter, Knoxville.

THE CADILLAC GLASS CO., Detroit, Mich., has been incorporated with a capital of \$50,000 to manufacture glass products. The incorporators are Fred L. Stoker, Ray L. Martin and Henry J. Berndt, 1147 Marlborough Ave.

THE EDEA OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$150,000 to manufacture petroleum products. The incorporators are E. A. Rany, E. W. Butcher and N. E. Canfield, Los Angeles.

THE FERRO CHINA BLOTTO CO., New York, N. Y., has been incorporated with a capital of \$15,000 to manufacture chemicals and chemical byproducts. The incorporators are M. M. Hirsch, D. B. Goodman and F. E. Mandel, 44 Cedar St.

THE CRYSTAL OIL CO., 407 Milliken Bldg., Decatur, Ill., has been incorporated with a capital of \$25,000 to manufacture oil products. The incorporators are C. M. Lamson, Thomas T. Roberts and William L. Shellabarger, Jr.

THE PROVIDENCE CHEMICAL CO., 51 Empire St., Providence, R. I., has filed notice of organization to manufacture chemical products. Herman M. Davis heads the company.

F. C. DONOVAN, INC., Boston, Mass., has been incorporated with a capital of \$10,000 to manufacture leather products. E. Barton Chapin is president; R. J. White, secretary; and J. Frederick Mann, 83 Gainsboro St., treasurer.

THE CHELSEA BRICK CO., Chelsea, Okla., has been incorporated with a capital of \$50,000 to manufacture brick and other burned clay products. The incorporators are Leon C. Merritt, J. A. Morrison, Chelsea; and W. L. Buckles, Okmulgee, Okla.

THE HOWE SPECIALTY CO., 191 Murray St., Newark, N. J., has filed notice of organization to manufacture rubber products. Walter J. Leatherow, 5 Thomas St., heads the company.

THE STANDARD PORCELAIN ENAMELING CORP., New York, N. Y., has been incorporated with a capital of \$22,500 to manufacture porcelain enamelware products. The incorporators are N. Chusid, M. and E. Ullman, 517 West 149th St.

THE GOLDEN DOME OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are Charles Gardner, M. H. Pearson and J. M. Brunner. James E. Mahon is representative for the company.

THE STANDARD CARBIDE SALES CO., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture coal and tar products. The incorporators are S. Null, W. B. Ragatz and R. M. Smith, Plattsburg, N. Y.

THE C. H. FRIANT RUBBER CO., 417 West Franklin St., Baltimore, Md., has been incorporated with a capital of \$50,000 to manufacture rubber products. The incorporators are Charles H. Friant, Charles P. Thompson and Charles Hess, Jr.

THE ACME TILE CO., Passaic, N. J., has been incorporated with a capital of \$750,000 to manufacture building tile and other burned clay products. The incorporators are Albert W. Reese, Daniel E. Saal, Clifton, N. J.; and Thomas H. Hogan, Passaic.

THE CENTRAL PAPER BOX CORP., New York, N. Y., has been incorporated with a capital of \$5,000 to manufacture paper boxes and containers. The incorporators are M. Ruskin, A. Pinkham and M. Hirschorn, 25 Monroe St., Brooklyn.

THE CHEMICAL COSMETIC CO., Newport, R. I., has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical byproducts. The incorporators are Charles D. Campbell, 69 Levin St., Newport; Marcus F. Whitland and Jacob S. Blake.

THE ORIENT SPRAY CO., 230 Pleasant St., Baltimore, Md., has been incorporated with a capital of \$10,000 to manufacture disinfecting oils, chemicals, etc. The incorporators are Percy C. Thornton, John W. Krauss and Edwin J. Farber.

THE NATIONAL EXTRACT & CHEMICAL CO., Boston, Mass., has been incorporated with a capital of \$15,000 to manufacture chemicals and chemical byproducts. The incorporators are Samuel F. Ruskin, David Rosenfield and Morris Kramer, all of Boston.

THE PERFECTION PAINT & COLOR CO., Indianapolis, Ind., has been incorporated

with a capital of \$20,000 to manufacture paints, varnishes, etc. The incorporators are William McCabe, T. E. Madden, and T. J. Gannon, Indianapolis.

MOSEY & CO., INC., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture oil products. The incorporators are R. F. Thomas, C. E. Moser and A. D. Emil, 1168 Fifty-third St., Brooklyn, N. Y.

THE ROCHESTER RUBBER CEMENT CO., Rochester, N. Y., has been incorporated with a capital of \$10,000 to manufacture adhesive products. The incorporators are J. T. Voll, G. A. Veomett and F. E. Frey, Rochester.

JAMES A. MILLER, INC., New York, has been incorporated with a capital of \$20,000 to manufacture chemicals and chemical byproducts. The incorporators are C. Pechner, E. H. Reichman and James A. Miller, 368 Greenwich St.

Capital Increases, Etc.

THE INTERSTATE CORRUGATED BOX CO., 790 Grand Ave., Brooklyn, N. Y., manufacturer of corrugated paper boxes, etc., has filed notice of increase in capital from \$100,000 to \$500,000.

THE WULBERN FERTILIZER CO., Charleston, S. C., has filed notice of increase in capital from \$100,000 to \$350,000. W. E. Jones is secretary.

THE VAN DYKE SMELTING & REFINING WORKS, 94 Van Dyke St., Brooklyn, N. Y., has filed notice of increase in capital from \$500,000 to \$1,000,000.

THE CORBIN BRICK CO., Corbin, Ky., has filed notice of increase in capital from \$30,000 to \$50,000.

THE CASTUS OIL CO., San Antonio, Tex., has filed notice of increase in capital from \$30,000 to \$100,000.

THE EBENEZER OIL CO., Wellsville, N. Y., has filed notice of increase in capital to \$100,000.

THE VASSAR FOUNDRY CO., Vassar, Mich., has filed notice of increase in capital from \$100,000 to \$200,000.

THE MORTON SALT CO., Port Huron, Mich., an Illinois corporation, has filed notice of increase in capital from \$1,500,000 to \$4,000,000.

THE UNITED STATES COLOR CARD CO., 632 Sherman St., Chicago, Ill., has filed notice of increase in capital from \$5,000 to \$50,000.

THE KENNELLY PAPER CO., 200 Fifth Ave., New York, has increased its capital to \$100,000.

THE STANDARD PAINT CO., Woolworth Bldg., New York, a New Jersey corporation, has filed notice of change of name to the Ruberoid Co.

THE DOVAN CHEMICAL CORP., a Delaware corporation, has filed notice of organization to operate in New York. R. G. Thach, 120 Bway., is local representative.

THE INTERSTATE RUBBER CO., 217 Smith St., Perth Amboy, N. J., has filed notice of dissolution under state laws.

THE STANDARD OIL CO. OF CALIFORNIA, 200 Bush St., San Francisco, has filed notice of increase in capital from \$100,000,000 to \$115,000,000.

Industrial Notes

H. S. GREENE has been elected vice-president in charge of sales for the Barber-Greene Co., Aurora, Ill. Mr. Greene was formerly with the National Carbon Co. of Cleveland, O., where for several years he was assistant sales manager. He is a brother of W. B. Greene, vice-president and treasurer of the Barber-Greene Co. and has been a director of the company for some time.

THE NORTH AMERICAN CAR CO., which operates a fleet of 1,050 tank cars between the Oklahoma and Kansas oil fields, has developed an oil terminal in Blue Island, Ill. Steel tank storage is under construction and will be available about July 1.

JAGENBERG MACHINE CO., INC., has moved its sales office to 2587 Third Ave., New York City, to have this office in the same building with the manufacturing plant.

HOGANAS BILLESOLMS AKTIEBOLAG, HOGANAS, Sweden, would like to correspond with American firms interested in buying chloride of aluminum, liquid technical or crystalline chemically pure.

New Publications

BOOKS

A TEXT BOOK OF CHEMICAL ENGINEERING. By *Edward Hart, Ph.D.*, professor of chemical engineering in Lafayette College, president of Baker & Adamson Chemical Co. Pp. 211; 200 figs. Easton, Pa.: The Chemical Publishing Co., 1920. Price \$4.

Literature in the English language on the fundamental operations and equipment used in chemical engineering has been woefully inadequate and scattered. Chemical engineers are therefore indebted to Prof. Hart for having made available data from his rich experience. It is admittedly not the last word on the subject, but is intended rather as a general introduction. The practical side of chemical engineering has advanced more rapidly than the theoretical, with the result that many operations are carried out every day in the plant which are but little understood from the point of view of the fundamental, physical and chemical phenomena involved. It is to be hoped that an increasing chemical engineering literature will encourage the study of these fundamentals, for in no other way can real advances be made.

In this book the author attempts to outline the different problems encountered in each phase of chemical engineering and to illustrate the types of apparatus which have successfully met these conditions.

The first chapter deals with what is probably the most important problem which the chemical engineer is called upon to solve—the choice of a construction material for apparatus. Cast iron, mild steel, silicon-iron alloys, copper, lead, aluminum, glass, fused silica, chemical stoneware and bakelite are discussed in turn. Location and construction of plants is next considered, followed by chapters on boilers and prime movers. Piping, including the handling of lead, stoneware and silica pipe, is treated briefly. The remaining chapters are devoted to operations and equipment: Crushing, dissolving, filtration, tanks, evaporation, crystallization, drying, distillation, absorption of gases, mixing and kneading, containers.

The illustrations are excellent and cover a wide range of chemical equipment.

APPLIED COLLOID CHEMISTRY—GENERAL THEORY. By *Wilder D. Bancroft, Ph.D.*, professor of physical chemistry at Cornell University. Pp. 345. New York: McGraw-Hill Book Co., 1921. Price \$3.

Prof. Bancroft needs no introduction to those interested in the subject of colloid chemistry. His thought in preparing this book is best expressed in his own words:

"The earlier books on colloid chemistry presented the subject empirically because no other method was then possible. While we do not now know much about gelatinous precipitates and jellies, the theory of the rest of the subject is in fairly good shape and consequently I have written this book deductively. . . . This volume on general theory should be followed by at least one volume on each of the following subjects: Silicate industries; paints and varnishes; plastics; fibers and dyeing; photochemistry and photography; petroleum industries; ore flotation and allied subjects; foods and beverages; soils and crops; biology and medicine."

GENERAL AND INDUSTRIAL ORGANIC CHEMISTRY, Part I, Second Edition. By *Dr. Ettore Molinari*, professor of industrial chemistry at the Royal Milan Polytechnic. Translated from the third Italian edition by Thomas H. Pope, F.I.C. Pp. 456; 254 illustrations, Philadelphia: P. Blakiston's Son & Co., 1921. Price \$8.

This volume treats from both general and industrial viewpoints the following classes of aliphatic compounds or methane derivatives: Hydrocarbons; halogen derivatives of hydrocarbons; alcohols and their derivatives; acids and their derivatives. In addition to the discussions of individual compounds descriptions of important industries are included at appropriate points. Among these may be mentioned: Illuminating gas; petroleum industry; alcohol and the fermentation industries; explosives; wood distillation; tartar and citrus industries.

MODERN WELDING METHODS. By *Victor W. Pagé*. Pp. 292; 113 illustrations. New York: Norman W. Henley Pub. Co., 1920. Price \$3.

Much practical information on welding operations will be found in this book. In addition to oxyacetylene and electrical welding chapters are included on the thermit and its applications, soldering and brazing, forge welding and heat treatment of steel.

CHEMISTRY OF PLANT LIFE. By *Roscoe W. Thatcher, D. Agr.*, dean of the department of agriculture and director of

the agricultural experiment stations, University of Minnesota. Pp. 268. New York: McGraw-Hill Book Co., Inc., 1921. Price \$3.

VITAMINES. By *Benjamin Harrow, Ph.D.*, associate in physiological chemistry, College of Physicians and Surgeons, Columbia University. Pp. 219; 8 charts. New York: E. P. Dutton & Co., 1921. Price \$2.50.

THE PLATINUM METALS. By *A. D. Lumb*, lately of the scientific and technical department, Imperial Institute. Pp. 63. London: John Murray, 1920. Price 3s. 6d.

This is one of the monographs on mineral resources with special reference to the British Empire prepared under the direction of the mineral resources committee of the Imperial Institute, with the assistance of the scientific and technical staff.

GOLD. By *Benjamin White*. Pp. 128, illustrated. London and New York: Sir Isaac Pitman & Sons, Ltd., 1920. Price \$1.

LEAD. By *J. A. Smythe, Ph.D.* Pp. 120; 17 illustrations. London and New York: Sir Isaac Pitman & Sons, Ltd., 1920. Price \$1.

These two little books form part of a series on common commodities and industries numbering about forty-five volumes at the present time. The treatment of each subject is brief and popular, the aim being to present a general rather than a detailed or technical survey.

MECHANICAL WORLD YEAR BOOK, 1921. Pp. 328; 93 illustrations. Manchester: Emmott & Co., Ltd. 1921. Price 2s. 6d.

MECHANICAL WORLD ELECTRICAL POCKET BOOK, 1921. Pp. 306; 108 illustrations. Manchester: Emmott & Co., Ltd., 1921. Price 2s.

FINDING AND STOPPING WASTE IN MODERN BOILER ROOMS. Second edition. Pp. 414, illustrated. Philadelphia: H. S. B. W.-Cochrane Corp., 1921. Price \$1.

As the title would indicate, this is a compilation of data from various sources on fuels, combustion, heat absorption, boiler efficiency, boiler testing, boiler plant proportioning and management. An immense amount of information is presented in a most usable form.

THE ORIFICE METER AND GAS MEASUREMENT. By *Willis C. Brown and Malcolm B. Hall*. Pp. 112, illustrated. Foxboro, Mass.: The Foxboro Co., Inc. Price, cloth \$3.50; leather \$4.50.

Manufacturers' Catalogs

THE CUTLER-HAMMER MFG. Co., Milwaukee, Wis., is distributing a four-page leaflet and an 8-page folder. Both of these publications are illustrated with views of space heaters installed in airplane hangars, crane cabs, valve houses, etc., and give lists of uses to which these heaters have been put.

PAWLING & HARNISCHFEGER Co., Milwaukee, Wis., announces a new edition (dated January, 1921) of its Bull. 5X, on the P. & H. Excavator-Crane No. 205. This bulletin describes the many and various uses of this general utility cranes, the photographic illustrations showing the excavator at work, equipped with a digging bucket, a back-filling scraper bucket, clamshell bucket, lifting magnet, special grapple for lumber and sling chains. Details of construction, specifications and operation are also included.

REPUBLIC CARBON Co., INC., Niagara Falls, N. Y., has issued a booklet on "Republic Electrodes." Illustrations are given of the various types of furnaces using the many sizes of electrodes, together with descriptions of the electric furnace, the electrode, manufacture, desirability of electrode, electrode consumption, making of joints and sizes. Tables are given of tensile strength of metals, composition of some typical engineering alloys, international atomic weights, melting points of various refractories, heat units, etc.

BAUSCH & LOMB OPTICAL Co., Rochester, N. Y., has issued a new projection catalog. This complete catalog of projection apparatus, which is the first this company has been in a position to publish since 1916. Of particular interest is the new model BC Balopticon for lantern slides, the projection of large opaque objects, the improved apparatus for microscopical projection and the more general application of the gas-filled mazda lamp.

E. F. HOUGHTON & Co., Philadelphia, Pa., had an investigation made by its research staff as to the causes of skin sores and boils among metal workers which has been

published in booklet form. The foreword, by Charles E. Carpenter, president of the company, outlines and summarizes the main features in plain, non-scientific language, easily understood by the practical man. He says: "While it is recognized that even this comprehensive work is not conclusive, it is nevertheless thoroughly practical. Wherever the suggestions for the prevention of infection have been applied in a common-sense manner the prevalence of infection has been cut down, and in some cases eliminated."

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN PAPER & PULP ASSOCIATION will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN WELDING SOCIETY, METROPOLITAN SECTION, will hold its regular meeting April 19 at the Engineering Societies Building, New York City.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

ASSOCIATION OF SCIENTIFIC APPARATUS MAKERS OF THE U. S. A. will hold its meeting at the Hotel Raleigh, Washington, D. C., April 14 to 16.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon April 26 at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY will hold its annual meeting at the Waldorf-Astoria and Hotel Astor, N. Y., April 11 to 14.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Prevention of Food Waste

Aim of Research Institute

THE happy-go-lucky manner in which this country has blundered through every war in which it has ever engaged indicates that the forefathers adopted a fitting motto, "In God we trust." With the exception of maintaining a Navy and a skeleton of an Army, we have never made any preparation until actual hostilities were begun.

In the matter of food supply for our forces in the field we have been notoriously and sometimes criminally lax. Fortunately the commissariat was arranged better in the late war than in the conflict with Spain, which tarnished many reputations, though it fattened some pocketbooks. But feeding the army in the field is only a small part of the problem. There is the vast army at home whose work in winning a war is not less important than that of the fighting forces. HERBERT HOOVER and the Allied food administrators faced a task as hard as that of any general on the firing line—that of seeing that food was produced in sufficient quantities and distributed so as to insure the maximum efficiency. Things were ordered differently in Germany. There the whole matter had been thought out and when the war came the system of feeding the industrial army worked like the well-oiled machine it was.

When the food administrators of the Allied and associated countries met during the late war they agreed to do all in their power to secure a systematic study of this matter in their respective countries so that some kind of system might be available in another emergency. With the close of the war Mr. HOOVER did not forget this agreement. As there seemed to be no chance to get the Government to act in the matter, he went to work in his characteristic manner to get action in some other way. Due to his efforts the Carnegie Corporation has agreed to furnish the finances for a period of seven to ten years and the Food Research Institute of Stanford University has been brought into being. Its work will be divided into three groups, each in charge of a director. One group will study the economic and statistical features, another will study nutrition and the third will study the industrial side. Only one director has as yet been chosen, Dr. C. L. ALSBERG, who will be at the head of the third group. It is promised that the men appointed to the other directorships will be of equally high caliber.

It should not be necessary to wait for a war to prove the advantages of such a work as will be undertaken by the Food Research Institute. It is important in peace time that the industrial army—which takes in pretty nearly all of us—should be fed adequately and properly.

There is enormous waste in our system of food distribution, lack of statistics and other economic data and poorly organized knowledge of nutrition. Why

should we wait until a war or some national emergency compels us to investigate these problems and correlate the findings? The Food Research Institute will be a means for determining the facts. The mechanism for availing ourselves fully of the findings and putting them to practical use does not yet appear, but undoubtedly it will be evolved later, so that not only will the hopes of the founders be justified but a distinct service will result to the whole country.

Idealism Tempered

With Common Sense

IN THE INDUSTRIAL life of a young and growing nation such as this there is often a tendency to the superlative in ideal or ambition that cannot altogether be justified. This perhaps is the excuse for the existence of pessimists, much as we hate that sort of creature. It is well, however, without becoming a pessimist, that we should temper our ambitions and our idealism with a generous measure of common sense.

Industrially the application of this principle means a careful consideration of the relative merits of old and new processes. That a new process is technically successful is not enough; it must also be a demonstrated commercial achievement before any great credit can be given to it in "practical affairs." The new process or product must afford a sufficiently wide margin of advantage above the old or current practice in order to justify a certain measure of risk in its adoption. One must never forget that any new development may prove to have altogether unsuspected deficiencies or defects. A wider margin of apparent advantage is, therefore, necessary to offset such possible contingencies.

Moreover, if the new process or product requires new investment it is very important to have a margin of financial profit sufficient to provide for the amortization of the old equipment or investment which must be discarded. Industrially there is little fear that this last factor will be ignored, for the banker, to whom we all go for the last word regarding new developments, is very careful to have this phase of new investment carefully considered before he will arrange for loans.

The research man often has what appears to him brilliant developments to offer, but finds unsympathetic or inattentive listeners when he presents his ideas for commercial development. Perhaps he may avoid the embarrassment of premature presentation of his projects and secure a more sympathetic hearing if he will bear in mind that it is necessary to present a certain margin of advance before he can claim to have made any real achievement. If he will do so he will contribute not only more to industry but also more to the advancement of research itself. This is particularly true in circumstances where partially developed, "half-baked" research is presented for the approval of management. Naturally the manager after repeated

experience of this sort is inclined to look with doubt upon all new developments offered from the research department, a result most unfortunate to that department and to the management as well.

The Merit and Value of Ceremony

THERE was a quality about that celebration at the Chemists' Club on March 17 that makes an interesting subject for discussion. The conferring of honorary membership on eight great chemists was made a very formal occasion. Every word and every move were planned beforehand; nothing was done off-hand, and, thanks to Dr. BASKERVILLE, who was chairman of the committee of arrangements, an impressive ceremony was devised.

Well, what's the use of ceremony anyway? Men of science have neither the "livery of heaven" nor professional millinery. It is their principal business to think straight and to talk straight; their symbols represent definite concepts and not, like the astrologer's pointed cap, mystic twaddle, or even any claim of authority. They have no robes of office or insignia of power; they wield neither magic wand nor scepter. Why wouldn't it be the sensible thing, if a body of chemists wants to make someone an honorary member, for the secretary to write him a letter, telling him of the fact, and then to let it go at that? The men would know, and all the business would be completed without any fuss or feathers.

We think the authorities of the club were wise in their generation in taking the opposite view. We live by symbols. We raise our hand and take an oath and then we are "under oath." If we lie at such a time there are dire consequences awaiting us. When a judge mounts the bench he wears his robe of office. When a policeman goes upon his beat to keep the peace he dresses for the part he is to take and he wears a uniform with brass buttons and a shield. The President of the United States does not wear a uniform, but he is encompassed by the White House, which is an official symbol of place. When the president of a university confers a degree he doesn't dictate a letter and post it to the recipient; he confers the honor with great dignity and formality. It is right that a distinguished occasion should be characterized by a fitting and proper ceremony. It makes a picture, and it is a serious mistake to think that anybody is too old or too wise to want to see a picture, or even to take a part in it.

Science has suffered from its informality. We claim participation in affairs, but we do not very often dress the part that we claim. We need to impress upon the rest of the world the dignity of science. Ceremony and formality are the gestures of life.

At the meeting in question there were eight distinguished members of the club appointed to meet, each one, the new honorary member or his representative, to whom he had been assigned, to conduct him upstairs and present him to the president, to escort him to dinner, and after dinner to escort him to the hall. Then when the president had called the meeting to order the chairman of the committee cited in alphabetical order, first those of the foreign nations present, then the Americans, by name, whereupon the escorting member stepped with his charge to the platform and formally presented him in words that had already been prepared. The president shook his hand, gave him a

beautiful certificate of honorary membership, and assigned him to his seat on the platform under his national flag.

There were no little jokes, nobody tried to be funny, and no one was embarrassed. Or if anybody was he was not placed in a position to be ridiculous. We believe that all who were present will remember the occasion as one on which the things which were done were done right.

Popular Appeal In Industrial Reels

THE people are the audience of the moving picture shows. They pay the price of admission primarily for amusement, which may be any form of mental satisfaction, comic, pathetic, educational, intelligent or otherwise. Propaganda films have a monopoly on the last three classifications, and especially of the last. Of the manufacturers HENRY FORD has probably propagandized most successfully, leaving the "otherwise" classification to his newspaper efforts. Ford reels have cultivated the acquaintance of the public by displays all the way from the marvels of the Detroit factory to touring through Florida in the winter and Canada in the summer à la Ford. Thousands of Fords on the highways could not begin to get the popular appeal that has been produced by these few thousand feet of picture reels.

Picture campaigns are costly, with negatives of interiors at four dollars per foot or second of display time. Movie operators ordinarily pay rent for the use of reels, but charge advertising rates for anything of a propaganda nature. Thirty thousand dollars per reel is said to be the average expense of covering the circuits throughout the United States, which makes the girls on the covers of our most popular magazines blush at their valuation.

Industrial movies in restricted circuits such as society meetings and educational institutions do not require silver wheels to put them across. While their function from the many selfish points of view may be limited, they have an influence that is well worth the effort spent to produce them.

Popularizing Science

AT LAST chemists can welcome an agency of publicity which is generously endowed for the promotion of scientific matters which does not propose as the first step of its activity to publish a new magazine. The scientific literature of the country is already so extensive that technical men are overburdened with new periodicals. In fact, as one engineer recently remarked, "The first function of a new association always seems to be to rent an office and hire a secretary; the second, to get out a new magazine." It is a great pleasure, therefore, to find that Science Service takes an entirely different stand in its proposal to work only through existing publications.

This new Service, which is headed by Dr. EDWIN E. SLOSSON, as editor, and HOWARD WHEELER, as manager, is generously endowed. It seems certain to succeed in its effort to popularize scientific information; and if we may judge its prospects of success from the splendid work which its editor has done in his volumes on "Creative Chemistry" and "Easy Lessons in Einstein" it is assured a splendid future.

Chemists and engineers will be well served by the existence of such an agency, for it will do much good in bringing these professional men before the general public through new channels. It is contemplated that the popular press, motion pictures and lectures will all be used in furthering the ideals of Science Service, which include instruction of "the public about the methods employed by science in discovering the secrets of nature," and also in bringing before the general public "the means by which industry and science operate to make available and distribute these supplies (the natural resources of the country)."

Even the technical men of today find it difficult to keep in touch with all scientific and technologic literature which is of value to them. It is easy to realize how much more difficult it is for the lay public to get even an elementary idea of many developments in which it is generally interested. If Science Service can even in a small degree satisfy the popular craving for reliable and yet intensely interesting information of new or spectacular developments it will have accomplished great good for the sciences and the branches of engineering with which it deals. Every effort of scientific and technical men to support the Service will, therefore, be well expended.

Rail Statistics For 1920

THE American Iron and Steel Institute reports the production of rails in the United States in 1920 at 2,604,116 gross tons, against 2,203,843 tons in 1919, about 1,900,000 tons in 1908 and 1914 and 3,977,887 tons in 1906, the record year for rail production. The production of late has been entirely of steel rails, the last iron rail production reported being 234 tons, in 1911. The rails made in 1920 were chiefly priced at \$45 for bessemer and \$47 for open-hearth, and higher, against prices of \$28 for bessemer and \$30 for open-hearth for many years prior to May 1, 1916.

The production of rails is not an index of railroad prosperity to anything like the extent that is commonly assumed. Of all classes of material bought by railroads, rails are among the least promising of increased revenue and the most dangerous to do without when needed. Ten years ago a much smaller tonnage of the total output was used for replacements than at present, while large tonnages were used for building new track. Long ago one function of branch lines of railroad was to remove the necessity of driving wagons through mud. The motor vehicle and highway improvement have filled that bill very largely, furnishing one of several reasons why additional branch lines are not built to so great an extent as formerly.

The decrease in the consumption of rails by the standard steam roads is really greater than appears from the production statistics. In 1906 total production was 3,977,887 tons, rail exports amounted to 328,036 tons, imports being 4,943 tons, while 284,612 tons of rails under forty-five pounds per yard were made, an unknown proportion of these light rails being exported. The domestic consumption of rails forty-five pounds and over was therefore about 3,500,000 tons. In 1920 production was 2,604,116 tons, including 489,043 tons of rails under fifty pounds per yard, exports were 594,634 tons and imports were 45,684 tons, making the domestic consumption of rails fifty pounds and over probably under 1,750,000 tons, or

a decrease of 50 per cent from 1906, whereas the total production declined by only about 35 per cent. The increase in the manufacture of light rails in the fourteen years, 60 or 65 per cent, is an interesting point.

The domestic consumption of standard section rails last year was of course almost wholly for replacement purposes. The building of new line dwindled to insignificant proportions several years ago, and the laying of additional track has been very small of late. The occasion for rail replacement is not in all cases simply normal wear. On account of heavier wheel loads the requirements in a rail increase. The old rail deteriorates rapidly and is replaced by a rail that will bear up better. The improvement is partly in quality and partly by increasing the section. Twenty years ago the 100-pound rail was a rarity, but in 1920 729,118 tons of rails were rolled in sections 100 pounds and over.

Titanium-treated rails came back a trifle in 1920, the tonnage so treated being 11,652 tons, against 6,207 tons in 1919 and 2,891 tons in 1918, the low year for titanium. In 1910 256,759 tons of rails were made with titanium treatment, but three years later less than one-fifth as many tons.

Theoretical Organic Chemistry and Synthetic Chemical Technology

ORGANIC chemists are becoming less and less dependent on their knowledge of college lecture black-board reactions showing the interaction of constituent groups of molecules taking place to suit the fancy of the crayonist. They are culling over the mass of descriptive records available in the literature and gradually evolving a few generalizations. If these prove to be useful they will sooner or later become a part of theoretical organic chemistry, and be applied in organic chemical technology.

The organic chemist, for example, knows that benzoic acid has not been prepared by the simple addition of carbon dioxide to benzene or monoxide to phenol. If he is a student of catalysis he may try to find a material that will induce carboxyl addition. It is accomplished in the synthesis of salicylic acid under the influence of the hydroxyl group and there is no evidence leading to the conclusion that results along catalytic lines cannot be obtained. Nevertheless sulphur and other catalyzer poisons are not removed from the purest commercial benzene to the extent of not being lethal in cumulative doses to such catalysts as nickel, and so the practical possibilities of such a process are indeed limited.

In substitution methods the organic chemist finds a much easier mode of attack. With toluene as the source the synthesis deals with simple atomic reactions, chlorine being substituted for the hydrogen in the radical with comparative ease and giving a product that can readily be hydrolyzed to benzoic acid. With benzene as the initial material the reaction deals with group molecular subdivisions and is very difficult to control. In this issue the investigation of Prof. McKEE and Dr. STRAUSS is being published not because it suggests a revolution in benzoic acid technology but as an example of diligent synthetic work along particularly difficult lines. The groups transferred are not atomically inactive to each other and of course the sulphonic group tends to be reduced and the other oxidized. The authors show considerable technique in handling the investigation and certainly have contributed in full measure to the literature in a spot where it is rather meager.

Readers' Views and Comments

A Compilation of American Dye Patents in Abstract Form

To the Editor of Chemical & Metallurgical Engineering

SIR:—Early in the development of the Color Investigation Laboratory the need was felt for a compilation of the American patents on dyes, and Miss Aida M. Doyle, at that time employed by this laboratory, undertook the task. It was our intention to publish it, but, owing to its size and the lack of funds available for such a publication from the Department of Agriculture, it has been found that it is impossible to do so. Consequently, the Bureau of Chemistry has decided to call the attention of those interested in such a work to the fact that the Color Investigation Laboratory has this in its files, where it may be consulted at any time. It should be borne in mind, however, that it is not possible for the laboratory to undertake patent searches.

The compilation is in the following form:

Each patent was abstracted under seven different headings, in order to make the compilation accessible from as many points of inquiry as possible. The abstract was typed on 3 x 5-in. cards, of which as many copies were made as was necessary. A separate file was made for each of the seven headings, so that it is completely cross-indexed, and any patent may be found in any one of seven different ways:

1. Scientific name, when known or given in the patent.
2. Intermediates used, with a very condensed statement of the method of manufacture.
3. Class of dye, according to Schultz's eighteen chemical classes.
4. Color of dye.
5. Method of use.
6. Fiber or material for which suitable.
7. Name of owner, and, in parentheses, name of patentee.

In making the first file, it was found that the scientific name was so seldom given and was apparently of so little importance that the file was finally arranged in strict numerical order. Besides the above information the number and date of patent are given, and, in the upper right hand corner, the Schultz number of the dye, when it is possible to locate it, together with the most common trade name, or the trade name given in the patent itself. Any additional information is added as a note at the bottom of the card. The chemical nomenclature and abbreviations used are those sponsored by *Chemical Abstracts*.

In order to make the explanation more intelligible, a specimen card is herewith reproduced.

No. 546,177

S. No. 607

9-10-1895

"Rheonin A."

1. Product like phosphine in properties

BENZOPHENONE condensed with *m*-PHENYLENE DIAMIN HCl and *m*-PHENYLENE DIAMIN by heating with ZnCl₂ in closed enameled vessel, on oil bath to 195-215 deg. The *m*-amino phenyl AURAMIN first formed combines with diamine to form the new dye.

2. Tetra methyl diamine

3. Acidic

4. Yellow, brownish-

5. Basic mordant

6. Cotton, leather

7. Badische (C. L. Müller).

It is to be seen that the abstracts, and the whole compilation in fact, are not intended to do away with the consulting of the patents themselves, but merely

to serve as a cross-index to them. At the same time the cards contain enough information to enable the user to decide which of several possible patents is the one he is looking for, without the necessity of handling the patents themselves, thus cutting down on their wear and tear as well as saving his time.

The compilation has been brought up to date of Jan. 1, 1921, by Max Phillips and Dr. L. D. Smith of this laboratory, and will be kept as complete as possible.

Any one desiring to make use of this compilation should either visit or address the Color Investigation Laboratory.

Senatorial Science

To the Editor of Chemical & Metallurgical Engineering

SIR:—The venerable Senators of the United States in high conclave assembled undertook on Feb. 25 last to discuss fertilizer materials. It had to do with an appropriation of \$86,000 "to determine possible sources of supply and methods of obtaining potash, nitrates and other natural fertilizers." The discourse of these learned men was so illuminating that I cannot forbear to copy some of their words of wisdom from the *Congressional Record*, in the hope that you will give your readers the benefit.

BY SENATOR WALSH: The Geological Survey has issued numerous bulletins concerning the supply of potash and nitrates . . . which have been referred to from time to time on the floor here. Bear in mind, I commend the investigation as one that ought to be encouraged, but we are certainly embarking the Agricultural Department in investigations that are particularly appropriate to mining operations.

SENATOR FLETCHER: In some respects it pertains to mining operations, but in other respects I think the investigation does not; because the Agricultural Department is making experiments now in the matter of developing potash, nitrates and acids for reducing potash into sulphate of ammonia, ammonium potash and so forth.

Here we have a balance of originality. Senator Walsh contributes the mining note on the fixation of nitrogen which disturbs Senator Fletcher's chemical conscience. As an offset to his conservatism, on the other hand, he gives us the new reaction of potash to ammonium sulphate and the new product, ammonium potash.

Senator Smith of South Carolina reminded his colleagues that the Department of Agriculture had made extensive investigations and reports in regard to obtaining potash from the kelp weed, to which Senator Walsh replied: "If the Senator from South Carolina will permit me, that is entirely proper. Kelp is an *agricultural product*. . . . There is also considerable quantity of potash discovered in reducing coal to coke. . . ."

We have made bold to italicize the new features of the learned Senator's comment.

Senator McNary thought they were drifting afield under the lead of Senator Smith. He did not think the appropriation indicated the performance of any

work in connection with processes for obtaining potash from kelp. "I think," said he, "the appropriation in the item under discussion is not even used for the purpose of studying the habits of the nitrates that may be obtained from leguminous plants." Here is a chance for cheap celluloid by the McNary process. Extract your cellulose already nitrated from the nitrated legumes, mix it with camphor, press it, and there you are! This should gladden the heart of Clarence Joyce if he sees it. Senator Smoot thought that the work should be done by the Bureau of Mines and the Geological Survey, because "Potash deposits are frequently found on public lands, for instance."

"Neither of these services actually makes experiments, as I take it," said Senator Fletcher. "They merely locate deposits and map and plot them, and that sort of thing, and show where the products possibly can be obtained, but the Department of Agriculture has a bureau which actually experiments with these different elements to determine the commercial value of the product."

Alas for Dr. Charles L. Parsons! Eheu, Dr. Cottrell! Væ, Dr. R. B. Moore! Senator Fletcher is in Washington; he is on the spot; and his remarks would seem to indicate that all these three gentlemen, as consecutive chief chemists to the Bureau of Mines, had been twirling their thumbs in idleness for years and years and years. We can hardly believe it. For a fact, we don't. Indeed, Senator Smoot corrected him. He told how the Bureau of Mines had spent hundreds of thousands of dollars for the investigation of "certain rock deposits in New Jersey for the purpose of extracting potash from the same." We take it that the "certain rock deposits" are green sands. He also said that the Bureau of Mines had "spent thousands and tens of thousands of dollars in developing the nitrate deposits in America." He probably referred to our aerial deposits of nitrogen.

Later in the discussion Senator Smoot said that "the great bulk of potash produced in the United States—and this statement will be as true in the future—has come from the extraction of potash or nitrates from the rocks which are found in the everlasting hills of the West." We can't help wondering whether those hills will be everlasting after "the potash or nitrates" have been taken out of them.

The argument as to the relative merits of the Agricultural Department and the Bureau of Mines would not down. Senator Fletcher thought the Department of Agriculture should determine "the source of fertilizer, the elements which enter into plant food, and the way to develop them and make them available to the producers of the food of the country on reasonable terms."

Senator Smoot objected, on the ground that "the scientists in the Department who have been educated to study questions relating to plant life, growth, development and other matters connected with the soil are not the ones to handle it. It takes men who have studied for years and years along a particular line, who have studied the geology of the country, and more than likely who have spent their early lives in the mines of the West. It takes practical men."

That looks like a swat at Dr. Alsberg of the Bureau of Chemistry. How many of his chemists can he point out who have spent their early years in the mines of the West?

Senator Walsh of Montana brought up the Searles

Lake deposits, and said that not only had the Geological Survey made repeated reports on it but that investigations by Congress had also been conducted and that the information so derived was also available.

A congressional investigation into salt brines would be interesting.

Senator Walsh resented the appropriation of \$5,000 to care for the machinery at the experimental kelp plant in California. "Private enterprise," said he, in regard to kelp, "is now engaged in the development of this source of supply of nitrate and it is not necessary for the Government to carry it on any longer."

This, Mr. Editor, is from the Senate of the United States; not the Senate of the Sovereign State of Nevada or of Arkansas. It is "the highest deliberative body in the world." Good Lord!

MARTIN SEYT.

Compensation of Chemists and Salesmen

To the Editor of Chemical & Metallurgical Engineering

SIR:—Mr. Ferguson's letter in your March 16 number headed "Compensation of Chemists and Salesmen" is interesting. Permit me to say, however, that while perhaps there are cases where chemists are insufficiently paid or are seemingly unappreciated, as is true in all walks of life, and that the law of supply and demand affects to some extent chemists' salaries, yet in the vast majority of cases I believe chemists are paid in direct proportion to the delivery they make.

When chemists are paid relatively low salaries it is probably because of their faulty training, their lack of practical horse sense and their inability to sense proportions. I am afraid Mr. Ferguson is not fully informed as to what "the average employer" is paying either his salesmen or his chemists, nor what these salesmen and chemists are *paying* their employer. At any rate, comparisons between chemists and salesmen are scarcely more illuminating than comparisons between chemists and college professors, twelve-dollar-a-day brick masons, or bank presidents. Business is a hard and ceaseless struggle and the employee, be he chemist, salesman or executive, who shows greatest results receives the greatest reward in the long run.

Temperature Conversion Tables

To the Editor of Chemical & Metallurgical Engineering

SIR:—We have had occasion to use almost daily your "Temperature Conversion Tables," as included in the Dec. 1 number of CHEMICAL & METALLURGICAL ENGINEERING, page 1075.

We have found in one small section of the table an error of exactly 1 deg. F. that is carried along for four consecutive temperatures. In converting from degrees Centigrade to degrees Fahrenheit the figures given are correct when converting from 15 deg. and from 20 deg. C. The error comes in the conversion from 16, 17, 18 and 19 deg. C. respectively, and amounts in each case to exactly +1 deg. F. Presumably the calculator of the conversions obtained the 15-deg. and 20-deg. C. values by use of the formula, and the values for the intermediate degrees by successive additions of 1.8. In the section in question the error came in adding 2.8 in one case and 0.8 in the other, instead of 1.8.

We call your attention to this error in the tables, because of their great excellence otherwise.

W. C. HOLMES.

Synthesis of Chlorine-Free Benzoic Acid From Benzene—I

An Investigation on the Synthesis of Chlorine-Free Benzoic Acid by Sulphonation of Benzene and Substitution by Carboxyl Group—Formate Fusion Method—Cyanide Fusion and Hydrolysis of Benzotrile Method*

By RALPH H. MCKEE, PH.D., AND FRANK A. STRAUSS

ALTHOUGH a variety of processes for the synthesis of benzoic acid have been proposed, the acid on the market today is made almost exclusively from toluene. The following investigation was undertaken to develop a commercial method for the synthesis of chlorine-free benzoic acid from benzene. An obscure and neglected reaction has been studied, modifications in the reaction conditions whereby a greatly increased yield is obtainable have been worked out, and some of the problems of the commercial application of the process have been touched upon. It is believed that a method is outlined herein for the manufacture of benzoic acid of high purity at a cost which compares favorably with that of the present method of production. The process, moreover, is of especial interest in connection with recent developments in the production of cheap cyanides from atmospheric nitrogen, for which new uses are being sought. It is also of interest in that it makes use of sodium benzene sulphonate, and thus offers a means of employing a part of the extensive idle equipment used in the manufacture of synthetic phenol during the war.

HISTORICAL AND BIBLIOGRAPHICAL REVIEW

Benzoic acid owes its name to its occurrence in gum benzoin. First mentioned in 1608 by Blaise de Vigenère, its preparation was described first by Scheele in 1755. Its structure was established by the classic work of Wöhler¹ and Mitscherlich.²

The processes used or proposed for the manufacture of benzoic acid may conveniently be classified according to the starting material.

MANUFACTURE FROM VEGETABLE AND ANIMAL SOURCES —PRODUCTION FROM GUM BENZOIN.

This was the first source of benzoic acid, and even today is said to furnish a small amount of the pharmaceutical product. The acid may be obtained by sublimation,³ by steam distillation,⁴ by extraction with alcohol⁵ or by digestion with alkali.⁶ A yield equal to 25 per cent of the weight of the gum is obtainable. Other resins, such as Siam, Palembang and gum acroides may be used.

PRODUCTION FROM ANIMAL SOURCES

The urine of herbivora contains small amounts of hippuric acid, $C_6H_5CONHCH_2COOH$, which on hydrolysis gives benzoic acid. About 1870 small amounts of the

acid were made commercially from this source in Germany and Austria,⁷ but the process has long since been abandoned. Benzoic acid has also been prepared from suint (crude wool grease).⁸

MANUFACTURE FROM PRODUCTS OF DISTILLATION OF COAL —FROM BENZENE

Direct synthesis by the Friedel-Crafts reaction from benzene and carbon dioxide in the presence of aluminum chloride is said to have been tried on a commercial scale in France.⁹

During the war, one American manufacturer converted aniline into benzonitrile by the Sandmeyer reaction (diazotization and treatment with cuprous cyanide), and hydrolyzed the nitrile to benzoic acid.

The manufacture of benzonitrile by the action of copper on phenyl isothiocyanate or diphenylthiourea has been proposed.¹⁰

Benzonitrile may also be synthesized by passing chlorobenzene over heated alkali cyanide or ferrocyanide.¹¹ As the best yields reported are 22 per cent, the method seems of little interest. A process has recently been patented¹² in which lower temperatures and the presence of a catalyst are specified.

FROM TOLUENE

Toluene may be oxidized to benzoic acid either directly or by chlorination with subsequent hydrolysis.

Among the agents for direct oxidation which have been proposed are:

- Air in the presence of a heated catalyst, such as: porous carbon or iron oxide;¹³ vanadium or molybdenum oxide;¹⁴ platinum.¹⁵
- Ozone.¹⁶
- Nickel oxide.¹⁷
- Nitric acid.¹⁸ The yields are fair, but the method is expensive. Two American manufacturers are using it in order to obtain a product free from chlorine.
- Potassium permanganate.¹⁹
- Manganese dioxide and acid. A wide range of

conditions has been patented.²⁰ The process is said to have been carried out abroad on a commercial scale.²¹

g. Chromic acid mixture. Toluene is oxidized in vapor form,²² or in the cold in the presence of iron, cerium or manganese compounds.²³

Manufacture by chlorination with subsequent hydrolysis has been the subject of much experimental work, and the literature abounds in references.²⁴ All three of the side-chain substituted compounds have been used.

Benzyl chloride, $C_6H_5CH_2Cl$, seems to be the starting material at present most generally used by American manufacturers. It is usually simultaneously hydrolyzed and oxidized with a warm slurry of bleaching powder. A number of variations of the procedure have been described. Thus Jessnitzer²⁵ heated benzyl chloride or a mixture of benzyl and benzal chlorides with lime and chalk. Savage and the Weston Chemical Co.²⁶ first reflux benzyl chloride with caustic soda or lime of milk and then oxidize with calcium or sodium hypochlorite. Leach²⁷ proposes heating with alkali and then passing in chlorine. Nitric acid may be used as oxidizing agent.²⁸

On hydrolyzing benzal chloride, $C_6H_5CHCl_2$, with alkali some benzoic acid is formed from the benzotrichloride present, and some also is formed secondarily from the simultaneous oxidation and reduction of two molecules of benzaldehyde. Considerable quantities of benzoic acid are obtained in this way as a byproduct in the manufacture of benzaldehyde.

Benzotrichloride, $C_6H_5CCl_3$, appears to be the starting material usually employed in German practice, and until recently in the United States as well; but at present the benzyl chloride method described above seems to be more generally used. The process of Schultze²⁹ has been widely employed. Benzotrichloride is decomposed with milk of lime in the presence of iron powder. Limpricht³⁰ hydrolyzed with water under pressure at 140 to 190 deg. This process was carried on commercially for a time.³¹ Espenscheid³² boiled with alkali containing solid matter to prevent the formation of two liquid layers. Janssen³³ has suggested the use of concentrated sulphuric or phosphoric acid in the cold. Jacobsen³⁴ prepared benzoyl chloride by heating with concentrated acetic acid and zinc chloride.

In the manufacture of saccharin considerable quantities of *m*- and *p*-sulphaminobenzoic acids are sometimes formed as byproducts. It has been proposed³⁵ to convert these compounds into benzoic acid by hydrolysis with superheated steam in acid solution.

FROM BENZONITRILE CONTAINED IN COAL TAR

The carbolic or creosote oil fraction of coal tar has been shown to contain a small amount of benzonitrile.³⁶

³⁶Kraemer and Spilker, *Berichte*, vol. 23, p. 78 (1890).

The manufacture of benzoic acid from this source by hydrolysis with alkali has been proposed.³⁷ The process was worked for a time at a plant near Vienna.³⁸

FROM NAPHTHALENE DERIVATIVES

Laurent and Castelraz³⁹ prepared benzoic acid commercially by distilling phthalic acid with lime about 1865. Laurent also manufactured benzoic acid from benzonitrile, prepared from phthalimide by heating with lime.⁴⁰ The Basler Chemische Fabrik has patented the production of benzoic acid from nitronaphthalene, nitronaphthols and phthalic acid by heating with alkali under pressure;⁴¹ also by fusing naphthols or other naphthalene derivatives with alkali.⁴² Gibbs and Conover state that benzoic acid is one of the products formed by the catalytic oxidation of naphthalene.⁴³

FROM PHENANTHRENE

The production of benzoic acid from phenanthrene by electrolytic oxidation has been proposed.⁴⁴

DISADVANTAGES OF THE PRESENT PROCESS

Although the details of the manufacture of benzoic acid are in general trade secrets, it is known that the difficulties of large-scale working are considerable. For example, chlorination at elevated temperatures (preferably with chlorine in the vapor phase), or in the presence of phosphorus or sulphur⁴⁵ chlorides, or in direct sunlight or ultra-violet light, must be resorted to in order to obtain the desired side-chain substituted compounds. Even then some compounds with chlorine in the ring are invariably formed.⁴⁶ Chlorination in sunlight or ultra-violet light is apparently the chief method in use in this country at present.

The sunlight process requires small glass units in order that the maximum reacting surface may be exposed to the light. The containers are expensive, fragile and a specially designed building is necessary, and production is dependent on the weather season. If ultra-violet light is used the units are larger, but expensive installations of quartz lamps are required; moreover, the yield is said to be not so good as with sunlight.

The process requires a large amount of chlorine, either in the form of gas or as bleaching powder. Although chlorine is a commodity for which new uses are being sought, its present cost is not low, and its purification, liquefaction, transportation and storage present problems which limit its usefulness. Moreover, this chlorine is largely converted into offensive waste products whose handling and disposition are accompanied by difficulties, particularly if bleaching powder is used.

The crude benzoic acid must be purified by sublimation, a difficult works operation. Even after purification the product is contaminated with appreciable amounts

⁴⁵Kyrides, U. S. Pat. 1,345,373.

⁴⁶Lubs and Clark (*loc. cit.*) give analyses of commercial chlorinated toluene such as is used in benzoic acid manufacture, origin not stated, but presumably typical. Two samples contained 2.9 per cent and 2.4 per cent ring chlorine respectively, corresponding to a chlorination in the ring of 13.2 per cent and 9.4 per cent of the toluene molecules present.

of chlor-compounds,⁴⁷ which are highly undesirable from a physiological viewpoint. The U. S. Pharmacopœia requirements as to chlorine content are rather indefinite, but it is well known that many lots offered as "U.S.P." contain appreciable amounts of chlorine. Benzoic acid free from chlorine commands a substantial premium on the market.

It is clear that these difficulties are inherent in the chlorination process, and although they may be minimized it is not likely that they can be eliminated entirely. The direct oxidation processes appear attractive because of their simplicity, but in practice they have not proved successful, partly because of the expense of the oxidizing agents and partly because of the poor yields. The other processes enumerated are manifestly of little commercial value, except perhaps under certain unusual conditions.

POSSIBILITIES OF A NEW COMMERCIAL SYNTHESIS

None of the processes starting with benzene hitherto used or proposed show much likelihood of commercial applicability. The Friedel-Crafts reaction offers interesting possibilities, but, like many similar syntheses, must await a cheap supply of anhydrous aluminum chloride. The process using aniline under ordinary conditions is far too expensive. The chlorbenzene reaction would probably not give a chlorine-free product, even if good yields were obtainable, which is doubtful.

The use of sodium benzene sulphonate as the starting material, however, offers more promise. The manufacture of this salt has been the subject of intensive study during the last few years. The details have been worked out with great minuteness, and its production has been carried out on an enormous scale with great success.

There are two known reactions for the synthesis of benzoic acid from alkali benzene sulphonate. They give benzoic acid either (a) directly, on heating alkali benzene sulphonate with alkali formate, or (b) through the intermediate production of benzonitrile, on heating the alkali sulphonate with alkali cyanide.

These reactions were first described respectively by Victor Meyer⁴⁸ in 1870 and by Merz⁴⁹ in 1868. Neither author gives many details as to conditions, yields, etc. Neither reaction seems to have received much attention since that date. The yields in both cases were apparently poor. In view, however, of the great improvement in yields resulting from the careful study of reaction conditions in the synthesis of phenol it was believed that a similar study might achieve considerable improvement in these reactions as well. The work which follows constitutes a record of this investigation and of the success obtained.

THE FORMATE FUSION METHOD

Although the reaction between potassium benzene sulphonate and sodium formate was first described by Meyer, the possibility of synthesizing the aromatic acid direct from the alkali sulphonate seems to have oc-

curred first to Merz.⁵⁰ In 1867 he heated a mixture of sodium benzene sulphonate and sodium carbonate to "over 400 deg." and isolated from the resultant charred mass a small quantity of material which exhibited many of the properties of benzoic acid. No later investigator makes any reference to this work of Merz.

Three years later Meyer mixed together equal parts of sodium formate and potassium benzene sulphonate, and heated the mass. Benzoic acid was recovered from the reaction mixture. Meyer wrote the equation as:

The yield was apparently small. He applied the method of synthesis to a number of other aromatic acids and used it to determine the position of the sulphonic acid groups in benzene disulphonic acid.

As a means of synthesizing the aromatic acids this method received some slight attention from later workers.⁵¹ However, because of the poor yields, better and less troublesome methods became generally employed and no reference to this reaction was found in the literature since 1886.

The work of Merz⁵² on fusion with sodium carbonate was repeated, following his directions as closely as possible. A charred mass resulted which contained no more than a possible trace of benzoic acid. Because of its inherent improbability no further attention was paid to this reaction.

Meyer's work⁵³ was next repeated with careful temperature control. A mixture of 50 g. sodium formate and 50 g. dry potassium benzene sulphonate was fused in an iron pot with constant stirring. Temperatures were measured with a base-metal thermocouple. No appreciable reaction took place below 290 deg.

The temperature of the melt was then raised to 300 deg. Vigorous foaming set in, accompanied by clouds of white smoke of pungent, disagreeable odor. The melt became viscous, semi-solid, and finally formed a dark brown cake. Heating was continued for fifteen minutes at 300 to 310 deg. The evolution of fumes having then almost ceased, the mass was cooled, dissolved in water, filtered to free from carbonaceous material, and acidified. A copious yellowish precipitate was formed, which after purification was identified as benzoic acid by the melting point of a sublimed sample, color reaction with ferric chloride, and odor on heating. Yield of crude benzoic acid was 3 g., or about 9 per cent of theory, based on the sodium benzene sulphonate used.

Meyer states in a footnote that sodium benzene sulphonate does not give this reaction. It seemed worth while to investigate this point. A run was made just as before, with the substitution of sodium benzene sulphonate for the potassium salt. At 350 deg. a reaction occurred as before. Benzoic acid was recovered from the reaction mixture. Yield, 2 g., or about 6 per cent of theoretical.

These experiments indicate that benzoate formation takes place only at a high temperature, and is accompanied by a great amount of decomposition. Benzoate formation takes place only at a relatively high temperature and is accompanied by a great amount of charring and the formation of decomposition products. Not only is the sulphonate charred and decomposed, but the sodium formate also breaks down above 290 deg.⁵⁴ It is prob-

⁴⁷Phillips and Gibbs [*J. Ind. Eng. Chem.*, vol. 12, p. 277 (1920)] give some data on crude benzoic acid and the losses accompanying its purification. Crude acid received from the manufacturer contained 7.57 per cent chlorine, calculated to a dry basis, of which 5.45 per cent was in the ring, corresponding to 23.9 per cent chlorobenzoic acid. The sublimed product contained up to 2.53 per cent Cl, although samples described as "very pure" containing 0.34 per cent Cl were obtained. Losses on sublimation ranged from 27 to 57 per cent of the acid originally present. These results were obtained in an investigation of a new method of sublimation and are not necessarily typical, yet they show how large the losses may become.

able that the disagreeable fumes evolved contain thiophenols and thio-ethers, since these products are readily formed by the interaction of sulphonates and reducing agents.⁵⁵ For these reasons it seems unlikely that the synthesis can have any practical value. The experiments are interesting, however, in that they show Meyer's observations on the behavior of the sodium salt to be in error. There is no appreciable difference in the reactivity of the sodium and the potassium salts other than that due to the higher temperature required to cause the former to react.

SYNTHESIS OF BENZONITRILE

Merz first distilled a mixture of equal parts of potassium benzene sulphonate and potassium cyanide from an iron retort and isolated benzonitrile from the oily distillate. He considered the reaction to be:

In addition to a yellowish red oil, ammonium carbonate and some ammonium cyanide collected in the receiver. The residue in the still contained carbon, potassium sulphide, potassium cyanate and potassium thiocyanate. The yield of benzoic acid formed from the nitrile on hydrolysis is given as 33 per cent, presumably based on the amount of potassium benzene sulphonate used.

Merz also applied this reaction to the synthesis of toluonitrile and naphthonitrile, and others have applied it to the synthesis of various aromatic and heterocyclic nitriles.⁵⁶ The yields in most cases were small, and the method has been quite generally abandoned in favor of the Sandmeyer reaction and others more suited to the organic laboratory. No one seems to have investigated the reaction carefully with a view to improving yields. Merz and Mühlhauser⁵⁷ described rather incompletely a few experiments in which the proportions of the components of the reaction mixture were varied. Witt⁵⁸ proposed the substitution of potassium ferrocyanide for the simple cyanide, claiming an increase in yield. Potassium ferrocyanide was used by a number of later workers in the synthesis of higher members of the series, and at least one laboratory manual⁵⁹ recommends its use. Tingle⁶⁰ in an investigation of various methods of synthesizing benzonitrile repeated Merz' work and obtained a yield of 26 per cent benzonitrile. Beyond these isolated instances the reaction seems to have received no study from its discovery to the present date.

OUTLINE OF EXPERIMENTAL WORK

A brief consideration of the reaction will show that the principal factors susceptible of variation are the temperature of the reaction, the pressure, and the composition of the reaction mixture. A series of runs was carried out in which the influence of each of these factors upon the yield of benzonitrile was determined. In most of these experiments sodium salts were used in place of potassium salts because of their greater importance from an economic point of view.

In addition, a study of the nature and quantity of the products of the reaction other than benzonitrile was made. The results obtained threw much light on the nature of the reaction and were of great practical importance, as they gave a basis for modification of the process whereby the yield was considerably increased.

In order to carry out under control a reaction of this sort an intimate mixing of the constituents and uniform heating of the mixture are essential. A closed steel vessel externally heated and provided with a delivery tube and stirrer was first tried. It was found, however, that the charge did not actually fuse, but only became pasty at the reaction temperature, whereupon the stirrer cut a channel for itself through the mass and became useless.

In the apparatus finally adopted the intimate contact required was obtained by mixing the materials beforehand, no stirring during distillation being attempted. Uniform and rapid heating was obtained by making the container relatively narrow and immersing it in a bath

FIG. 1. EXPERIMENTAL RETORT

or fused salts. As the reaction is exothermic, this form of apparatus quite effectually minimized the undesired rise in temperature which would otherwise take place.

The apparatus is shown in Fig. 1. It was made for the most part of pipe fittings. The charge was contained in a vertical steel cylinder 2 in. in diameter and 6 in. long. The chamber was provided with a delivery tube 12 in. long inserted in the side near the top and inclined slightly downward. The chamber was closed by screw caps at top and bottom, a thermocouple passing through a stuffing box in the upper cap.

The salt bath, an equimolecular mixture of sodium and potassium nitrates, was contained in a steel pot 6 in. in diameter and 8 in. deep. The pot was set in a flue formed by a steel cylinder 7 in. in diameter and 9 in. long heavily lagged with asbestos magnesia pipe covering. Gas heating was employed. The temperature could be maintained within 3 to 5 deg. without difficulty, and with careful attention control within 2 deg. was possible, which was the least reading of the pyrometer.

The temperature of the system was measured by base-metal thermocouples and a calibrated millivoltmeter. One couple was immersed in the fused bath in contact with the retort a little below its center. The other was

buried in the charge within the retort, the cold end projecting through the top cap. The cold ends of the thermocouples were maintained at a temperature close to that of the room, frequent measurements showing no variation greater than a degree or two. Hence no correction for this factor was required.

Normally the temperature within the retort during heating lagged behind that of the heating bath. When, however, the exothermic nature of the reaction was pronounced the inner temperature rose above that of the heating bath, as is shown by curves later on. Because of this discrepancy the outer temperature was taken as the criterion in all cases, the inner reading being used only as a check on the progress of the run.

The remainder of the apparatus was very simple. The delivery tube of the retort communicated with a large side-arm test tube in which the major portion of the liquid distillate collected. This receiver in turn was connected with an empty filter flask in which a small amount of distillate sometimes collected. When the evolved gases were examined they were collected over water in an 8-liter bottle. In the runs at reduced pressure the system was evacuated by a suction water pump.

MATERIALS AND GENERAL PROCEDURE

A high grade of commercial sodium cyanide, "sodium cyanide 96 to 98 per cent," was used. It was obtained in lump form, pulverized, and kept in stoppered bottles. Analysis after pulverizing showed a NaCN content of 94.19 per cent (by the Liebig method). This somewhat low figure is due at least in part to absorption of moisture, etc., during grinding.

The sodium benzene sulphonate was prepared from benzene by sulphonation, conversion into the calcium salt and careful conversion of the calcium salt to the sodium salt with sodium carbonate. The salt was powdered and dried at 120 deg. Its sodium benzene sulphonate content by the alcohol extraction method^a was 95.1 per cent.

The course of a run was generally as follows: The requisite amounts of cyanide and sulphonate were weighed out rapidly and transferred to a porcelain jar mill. Usually quantities of materials were chosen such that the total weight of the charge was about 180 g. The charge was then simultaneously ground and mixed by tumbling in the mill. After thorough mixing the contents of the mill was rapidly charged into the retort. The retort was then closed tightly, immersed in the salt bath, which had been brought to the proper temperature, and the pyrometers and collecting train adjusted. As soon as the outside temperature reached the desired point the log of the run was started.

Readings of temperatures, time, etc., were ordinarily taken every ten minutes. The heating flame was carefully adjusted to keep the outside temperature at the desired point. When no more distillate came over heating was discontinued, the distillate removed and treated as described hereafter, and the retort removed and opened. In some runs a portion of the charge was found unchanged in the upper cooler part of the retort, where it had been forced by the evolution of gases. In such cases the charge was removed from the retort, broken up, returned, and the run continued as before.

The experimental work on the formation of benzonitrile may be divided into two main parts:

- I. A detailed study of the products of the reaction.
- II. A study of the effect of variations in reaction conditions on the yield of benzonitrile.

THE PRODUCTS OF THE REACTION

The residue remaining in the retort was black, porous and friable, resembling soft coke. It was hygroscopic and usually had a slight odor of hydrogen sulphide. On treatment with water a black alkaline unfilterable liquid resulted, the color being due to colloidal carbonized material. The colloidal material was precipitated upon acidification or upon adding a salt of a heavy metal. The solution could then be filtered, and the filtrate was clear and colorless, or only slightly yellowish.

The analysis of this material presented many difficulties because of its complexity and because of its colloidal nature. Nevertheless satisfactory methods were finally devised. The results are believed to be quite as accurate as was consistent with the complex nature of the material and the manipulative difficulties of the analytical procedure. A brief description of the methods employed follows. Lack of space prevents discussion of many minor details of technique.

The residues contained, in addition to carbon, sodium carbonate, sulphate, sulphite, sulphide, thiocyanate and benzene sulphonate in varying proportions. Sulphate was determined gravimetrically on a portion after dissolving, acidifying, boiling vigorously and filtering out the insoluble carbonaceous matter. The latter was collected on a Gooch and weighed. To determine thiocyanate, a sample was dissolved in water, an excess of zinc sulphate added to precipitate sulphides, ferrocyanides and colloidal matter, the solution filtered, and the filtrate titrated with standard silver nitrate solution and ferric alum indicator after acidification.

Another portion of the sample was dissolved, treated with ammoniacal zinc sulphate, filtered, and sulphite determined in the filtrate iodometrically. The precipitate, containing the sulphide in the form of insoluble zinc sulphide, was transferred to an evolution flask, treated with hydrochloric acid, and the evolved hydrogen sulphide absorbed in ammoniacal cadmium chloride solution and determined iodometrically.

Cyanate was determined by hydrolyzing a sample with dilute acid (after the precipitation and removal of thiocyanate as the silver salt in acid solution) and determining the ammonia formed by distillation with alkali in the usual manner. To another sample a measured excess of standard acid was added, the solution filtered after an hour's standing, and the filtrate back titrated with alkali and methyl orange. From the data thus obtained the carbonate content was calculated, allowance being made for the acid consumed in hydrolyzing the cyanate and decomposing the sulphide present. Sodium benzene sulphonate was determined by extraction with alcohol after converting sodium cyanate and thiocyanate into the alcohol insoluble copper salts. Ferrocyanide when present was determined by the Williams method.^b

Data showing the composition of the residue under varying conditions are given later on, and an interpretation of these results is reserved for that time. It will be sufficient to point out now that reaction products of such complexity and deviating so widely from the composition expected from theory indicate that extensive side-reactions must occur during heating.

The oily distillate, which consisted mainly of benzonitrile, varied in color from a light greenish brown to a very dark brown, becoming darker and cloudy during the course of a run. It was found that a rapid and fairly clean separation of the benzonitrile from the higher boiling constituents of the oil could be effected by steam distillation. The two fractions thus obtained were examined separately.

The fraction volatile with steam accumulated during a number of runs was dried over calcium chloride. It had a pale straw color, the pleasant odor of benzonitrile, and density, $D_{15/15} = 1.021$ (Westphal). A 100-c.c. sample distilled from a 250-c.c. flask gave the distillation curves plotted in Fig. 2, thereby showing the liquid to be substantially benzonitrile.⁶³ In order to determine the nature of the other compounds present, the first and last portions of the distillate were examined separately.

The first few drops distilling over had a disagreeable odor resembling phenyl isocyanide. They were shaken with cold concentrated hydrochloric acid to hydrolyze any isocyanide present. The acid solution was separated from the oil, neutralized, and a few drops added to a bleaching powder solution. An intense violet-red coloration resulted, indicating the presence of aniline, formed by the hydrolysis of phenyl isocyanide.

The presence of phenyl isocyanide (b.p. 165 deg.) is not surprising, as it is known that the normal and isocyanide exist together in equilibrium at elevated temperatures.⁶⁴ Alkyl cyanides prepared by distilling alkyl sulphates with alkali cyanides are always accompanied by a small amount of the isocyanide. Phenyl isocyanate (b.p. 166 deg.) has an odor similar to phenyl isocyanide and on hydrolysis would also give a test for aniline, but the density of the first 10 c.c. distilling (1.000) indicated the presence of phenyl isocyanate ($D_{15/15} 0.9775$) rather than the isocyanate ($D_{15/15} 1.092$).

The last portion was light yellow in color and deposited white crystals in the condenser and receiver. It had the odor and appearance of the first fraction obtained on distilling the oil non-volatile with steam. The crystals were identical with those separating from that fraction (gave same m.p., and m.p. of mixture was not lowered). The oil had the unmistakable odor of diphenylsulphide, the principal component of the fraction non-volatile with steam.

THE FRACTION NON-VOLATILE WITH STEAM

The residues from the steam distillation of the crude distillate were set aside. On standing a quantity of crystalline material separated out. The supernatant oil was poured off and the crystals retained for further examination. The oil was of a reddish brown color and had a rather pleasant sweet odor, density after drying over calcium chloride about 1.12. The upper curve, Fig. 2, was obtained on fractionating 133 g. of the dried oil from a 500-c.c. flask. All fractions of the distillate had the highly unpleasant odor associated with compounds of the thio-ether type.

The first and last portions of the distillate were cooled to -5 deg. and filtered to remove the white crystals which separated out. The crystals were washed with cold alcohol and reserved for further examination. The

filtrates and middle fractions of the distillates were combined and refracted twice. Ten c.c. of a yellow liquid of unpleasant leek-like odor, b.p. 294 to 297, $D_{15/15} = 1.114$, was obtained.⁶⁵ Identification as diphenylsulphide was completed by oxidizing a portion to diphenylsulphone (m.p. 125 deg.) by the method of Stenhouse.⁶⁶

The crystals separating from the crude oil on standing were washed with cold alcohol and recrystallized several times from benzene. From 4 g. of the original residue about 2 g. of a substance having the following properties was finally obtained: difficultly soluble in hot

FIG. 2. DISTILLATION CURVES

alcohol, moderately soluble in cold and very soluble in hot benzene, crystallizing in hemispherical masses of white crystals, m.p. 158 deg. These properties⁶⁷ correspond closely to those of diphenylene disulphide ($C_6H_5)_2S_2$. Lack of material prevented more complete identification. The crystals separating from the high-boiling fraction of the oil non-volatile with steam were also found to be diphenylene disulphide.

About 1 g. of crystalline material separated from the low-boiling fraction of the oil non-volatile with steam. After several recrystallizations from alcohol about 0.5 g. of short white needles, sparingly soluble in cold and very soluble in hot alcohol, soluble in benzene, m.p. 177 to 180 deg., was obtained. Lack of material prevented further identification.

To sum up: In addition to benzonitrile the following substances were isolated from the oily distillate: phenyl

⁶³ $D_{15/15}$ for benzonitrile = 1.0102 [Schneider, *Z. Physik. Chem.*, vol. 19, p. 157 (1896)]; b.p. 760 mm.: 190.7 deg. (Schneider); 191.3 deg. [Timmerman, *Bull. Soc. Chim. Belg.*, vol. 24, p. 244 (1910); *Chem. Centralbl.* (1900) II, p. 442].

⁶⁴Hoffman, *Annalen*, vol. 144, p. 114 (1867); Weith, *Berichte*, vol. 6, p. 213 (1873).

⁶⁵B.p. of diphenylsulphide 296.5 deg., $D_{15/15} = 1.1185$ [Perkin, *J. Chem. Soc.*, vol. 69, p. 1243 (1896)].

⁶⁶*Annalen*, vol. 140, p. 290 (1866).

⁶⁷Stenhouse, *Annalen*, vol. 140, p. 284 (1866); vol. 149, p. 247 (1869).

isocyanide; diphenylsulphide; solid, m.p. 177 to 180 deg., slightly volatile with steam; solid, m.p. 158 deg., b.p. over 300 deg., apparently diphenylene disulphide.

It might be well at this point to consider the source of some of these byproducts. The significance of phenyl isocyanide has already been discussed. Compounds of the thio-ether and thiophenol type are common products of the thermal decomposition of aromatic sulphonates. Stenhouse⁶⁸ isolated diphenylsulphide and diphenylene disulphide as well as thiophenol from the products of dry distillation of sodium benzene sulphonate. It is interesting to note, however, that he obtained considerable diphenylsulphide on distilling from a copper vessel, and considerable thiophenol, but little or no diphenylsulphide when an iron container was used. In the present experiments, though an iron vessel was employed, considerable diphenylsulphide was obtained. The isolation of thiophenol from the first fraction of the steam distillate was attempted, a portion being treated with alcoholic mercuric chloride after the usual method.⁶⁹ The result was negative. On applying the color test for thiophenol a few drops of the fraction gave only a faint coloration with concentrated sulphuric acid on long standing. Accordingly it is evident that the mechanism by which diphenylsulphide forms on distilling a mixture of sodium benzene sulphonate and sodium cyanide differs essentially from that by which sodium benzene sulphonate alone decomposes on heating.

This is also indicated by the temperatures at which the two reactions take place. It was found that sodium benzene sulphonate alone can be held at the temperature of these experiments (410 to 440 deg.) indefinitely without decomposition. Only on heating above its melting point (450 deg.) does decomposition take place. The presence of sodium cyanide and of the products of the benzonitrile reaction seems to be responsible, at least in part, for the formation of sulphur compounds. The following are possible, perhaps even probable, reactions by which diphenylsulphide might be formed.

The cyanide might well act as a reducing agent.

More sulphonate might react with the sodium sulphide thus formed:

Although the latter reaction has never been described, it would be in keeping with the behavior of the benzene sulphonates. Thus Spring and Krafft⁷⁰ prepared diphenylsulphide by the distillation of a mixture of sodium benzene sulphonate and phosphorus pentasulphide. Stadler⁷¹ distilled sodium benzene sulphonate with potassium sulphhydrate and obtained thiophenol.

THE GASEOUS PRODUCTS

A large volume of gas was always evolved during distillation, a part of which condensed in the cooler portion of the receiver to form a sublimate of solid ammonium salts. The following compounds were identified in the gases evolved: ammonia, carbon dioxide, hydrogen sulphide, hydrocyanic acid, water.

In order to determine the composition of the gas quantitatively a run was made in which it was collected over a large volume of water, in which the greater

TABLE I. ANALYSIS OF EVOLVED GASES

part was soluble. The solution thus obtained and the gas over it were then analyzed for NH₃, CO₂, H₂S and HCN. The water content of the gas could not be readily obtained. The results, expressed in per cent by weight, are given in Table I.

SUMMARY AND DISCUSSION

It is evident from these experimental results that the formation of benzonitrile is accompanied by extensive side-reactions which give rise to a great variety of byproducts. These byproducts give some clue to the processes involved, which are obviously complex, but probably belong to two groups—namely, those due to the reducing action of sodium cyanide, and those due to the thermal decomposition of the organic compounds present.

The reducing power of cyanides at high temperatures is well known. This reducing action would result in the formation of diphenylsulphide according to the reactions already given. In this connection it is interesting to note that no sodium cyanide remained in the residue from the retort, even when a large excess was originally present.

The pyrogenic decomposition of sodium benzene sulphonate would result in the formation of water, hydrogen sulphide, carbon, and sodium carbonate or sulphide. It is true that pure sodium benzene sulphonate does not decompose appreciably at the temperature of the reaction, but Stenhouse has shown that different substances catalyze this decomposition in different ways, and it may well be that some of the other materials present exert a catalytic effect.

If water vapor were formed in this manner it would react immediately with the sodium cyanate formed from the sodium cyanide:

This would account for the fact that large quantities of sodium carbonate, but only small amounts of sodium cyanate, were usually found in residue.

To sum up: In addition to the main reaction in which benzonitrile is formed, side reactions of two general types occur: (a) reduction of the sodium benzene sulphonate by the sodium cyanide, and (b) pyrogenic decomposition with the decomposition of the sodium cyanate formed in (a) and the consequent liberation of ammonia.

Part II will be published in a subsequent issue.

Peruvian Copper Production for Four Years

The monthly production of copper by the Cerro de Pasco Copper Corporation of Cerro de Pasco, Peru, for the past four years was as follows: 72,675,032 lb. in 1917; 81,906,000 lb. in 1918; 58,124,000 lb. in 1919; 63,128,000 lb. in 1920. According to the foregoing figures, the production of copper in 1920 showed an increase of 5,004,000 lb. as compared with 1919. The production in 1920, however, was 18,778,000 lb. less than in 1918 and 9,547,032 lb. less than in 1917.

The Vapor Compression System of Evaporation

Description of the Autovapor Type of Evaporator Recently Introduced Into Practice in Europe—Comparison With Multiple Effect Evaporators Heated by Primary Heat, in Favor of New Design

By GUSTAV CARLSSON

Chemical Engineer, Brooklyn, N. Y.

BEFORE describing the vapor compression system of evaporation, the first great advance made in the evaporation of liquids might well be mentioned. Pecqueur in 1834 invented the multiple effect system, which resulted in an enormous saving for many industries in concentrating their products from aqueous solutions. The sugar industry adopted it, and as a matter of fact the improvements since that time are very closely connected with the development of that industry. Modern evaporators bear little resemblance to the original apparatus. As time went on other chemical industries have introduced multiple effect evaporators to concentrate the liquors containing valuable products in solutions.

Although multiple effect evaporation in the past has been one of the most important processes in the chemical industries, its weak points from an economical as well as a technical point of view must not be overlooked. In order to produce the necessary steam to operate it, fuel must be consumed. The cost of evaporation depends upon the price of this indispensable fuel. In order to utilize the heat at all economically several units must be put in series. With two units in series, we are able theoretically to evaporate 2 lb. of water per pound of steam, in a triple effect 3 lb. per

Switzerland began manufacturing evaporators which are sold under the trade name of "Autovapor." They have been in use in a great number of plants in Europe. The results of operation indicate that it has some important advantages and that it will probably have continued and successful development in the chemical industry. To a large extent its progress is due to the development of the high-speed compressor, by which the problem of compressing the vapors has been solved in a very satisfactory manner.

In evaporating 1 lb. of water at 212 deg. F. and atmospheric pressure, about 970 B.t.u. is used, or practically one-tenth of the heat obtained from 1 lb. of coal. Instead of conducting the water vapor to the atmosphere, where it will be lost in space, we may compress it to about 3 atm., raising the temperature correspondingly to about 271 deg. F., and have useful energy available. The heat energy of the vapor has the energy of the work of compression added to it and if the compressed vapor is passed through a coil submerged in the liquor being evaporated, the vapor will condense, delivering its latent heat, whereupon more water will be evaporated from the liquor. Continuous evaporation is obtained by the addition of the mechanical energy required for compression.

Lines of Design of Apparatus

The liquid to be evaporated is placed in the evaporator, Fig. 1, and is heated to the boiling point by the steam coil 2. As soon as boiling has begun, the steam feed to the coil is cut down and the water vapor is drawn from 1 by pump 6, driven by the electric motor 15 and compressed through pipe 7 into coil 8. The compressed vapor condenses in the coils and delivers its heat of condensation and superheat, which from that time maintains ebullition in the evaporator. The condensate is discharged through pipe 9 into preheater 10, preheating the liquid charge entering the evaporator through coil 12 and the pipe 13, and then is emptied through pipe 14. The electric motor driving pump 6 consumes but a fractional part of the heat energy equivalent for evaporation. The evaporation of 1 lb. of water at atmospheric pressure requires about 970 B.t.u. To increase the pressure from 1 to 3 atm. and at the same time increase the temperature to about 271 deg. F., an amount of energy equivalent to 106 B.t.u. is required, measured at the shaft of the pump with the efficiency taken into account. This 106 B.t.u. is equivalent to slightly more than 10 per cent of the heat energy flowing through the pump and used in the evaporation. The best results are obtained with dilute solutions. When dealing with concentrated solutions, conditions are not so favorable, because the boiling points of the solutions are higher than those of the solvents.

FIG. 1. SKETCH OF AUTOVAPOR SYSTEM

pound of steam, and so forth. In practice these figures of course do not hold, being 1.2 and 2 instead of 2 and 3, with apparatus having a capacity of 2,200 lb. of water evaporated per hour.

Many suggestions on new evaporation methods have been made and tried during recent years, but all of them have failed until quite recently. In 1918 a firm in

One of the earliest types of Simplex-Autovapors—i.e., with single boiling pan and used in concentrating sodium hydroxide liquor—was thoroughly controlled by Prof. Stodola at the Institute of Technology in Zürich, Switzerland. The apparatus had been running for 1½ months and had not been cleaned prior to the test. The capacity was 2,200 lb. of water evaporated per hour. He stated the efficiency to be 36.2 to 37.7 lb. of water evaporated per kw.-hr., the liquid being concentrated from 7 deg. to 23 deg. Bé. This means that although the concentration was considerable, the evaporation is from 11.2 to 11.7 times that obtained by direct conversion of the electric current consumed into heat.

This result is particularly interesting because the apparatus was not thoroughly insulated against heat losses. The temperature of the feed liquor was about 68 deg. F. and the temperature of the condensate when leaving the system was 176 deg. F. Using a preheater, much better results should be obtained. The capacity of the apparatus was about 2,200 lb. of water evaporated per hour, consuming about 50 kw.-hr. In spite of the high concentration of the liquor, the condensate was very pure, containing but 0.002 g. NaOH per liter. This indicates that with this type of equipment distilled water is obtained with a degree of purity which an ordinary evaporator cannot deliver.

The arrangement of a small installation with a capacity of 2,200 lb. of water evaporated per hour is shown in Fig. 2.

In order to reduce heat losses, the different units

FIG. 2. SKETCH OF A PLANT INSTALLATION

of the apparatus are built closely together and the compressor and the motor are in the same room, because no corroding fumes were evolved there.

Among installations that have been erected for chemical purposes, some are used for concentrating sodium sulphite liquor containing more than 80 per cent water. The concentrated liquor is used as a binder for coal

briquets, as a leather-filling substance, in producing alcohol, and so forth. This liquor is particularly adaptable, as the rise of the boiling point is small with increase of concentration, amounting to only from 5 to 8 deg. F. due to the high molecular weight of the dissolved substances. Most liquids that are evaporated, however, have much higher increments in their boil-

FIG. 3. ENERGY DIAGRAM

ing point upon concentration, sodium hydroxide liquor being about 32 deg. F., saturated common salt solutions 16 deg. F. These increments of boiling temperature upon concentration must be taken into account when calculating the degree of compression of the vapor so that the increase in the temperature of the compressed vapor under the operation will compensate for the rise of the boiling point. In addition a temperature difference has to be established between the compressed vapor in the coil and the liquid to obtain a sufficient rate of heat transmission.

In the dye industry also apparatus mostly of the Simplex type have been installed, evaporating from 35.3 to 38.6 lb. of water per kw.-hr. continuously and they have in long runs produced liquor of 34 deg. Bé. It was necessary due to acid fumes to install the motor and the compressor in separate rooms. The capacity is about 2,760 lb. and the efficiency 35.3 to 39.8 lb. of water evaporated per kw.-hr. The liquid is evaporated to the same viscosity as sirup.

Returning to the test made by Prof. Stodola, the following data were obtained:

The rise in the boiling point was from 3.6 deg. to 12.6 deg. F. During a 5-hr. run 11,590 lb. of water was evaporated from the liquor, using 271.41 kw.-hr. to run the compressor and in addition 1,598 lb. of steam. The rate per hour gives: 2,320 lb. of water evaporated, using 54.28 kw.-hr. and 320 lb. of steam, or 42.6 lb. of water, evaporated per hour, neglecting the steam, and 37.7 lb., considering the steam used, respectively.

ENERGY CONSUMPTION

Fig. 3 shows the results diagrammatically. As a matter of fact, in the preheater only 4.0 per cent of the heat was recovered, while at the same time 10.7 per cent was removed by the condensate. In this case, however, the preheater was not enlarged, as the 10.7 per cent of heat in the hot condensate available could be used in other departments of the plant. As a result we might see that of the 12.4 per cent of steam added only 1.7 per cent has to be considered as a real loss due to insufficient heat insulation. We may now state that the test gave the following results: Using 271.41 kw.-hr. and 1,598 lb. of steam, 11,590 lb. of water was

evaporated from the liquor and in addition 13,235 lb. of distilled water was obtained at a temperature of 176 deg. F.

How to utilize the heat of the condensate has to be determined in each particular case. Being very pure, it may be used directly in the manufacturing process. In other cases an efficient preheater may be installed, and no doubt will pay for its investment. Summarily it may be seen that even such a small apparatus can be run economically.

Regarding the construction details of this evaporator, the following is quoted from the English patent: "The evaporator has vertical heating channels formed by annular hollow heating bodies, arranged concentrically one within the other. The channels are provided with scrapers, which extend from above and operate in a resilient manner on the vertical walls. The scrapers are of clamp shape, removable and mounted on a horizontal beam, which is rotated about a vertical axis."

COMPARISON WITH EFFECT TYPES

The following figures are given for purposes of comparison of this method with a multiple effect system, based upon the results stated above and with a capacity of 2,200 lb. per hour. With a triple effect evaporator of this capacity 2 lb. of water may be evaporated per lb. of steam:

a. Using a vapor compression system evaporator, driven by electrical energy: Evaporating 2,200 of water, 51.6 kw.-hr. is necessary. Referring to previously stated results to cover heat losses: $\frac{1.7 \times 305}{12.4} = 41.7$ lb. of steam is necessary. Assuming 8.5 lb. of steam per pound of coal, this corresponds to $\frac{41.7}{8.5} = 4.92$ lb. of coal.

b. Using a triple effect evaporator: The following quantity of coal will be necessary: $\frac{2200}{2 \times 8.5} = 129.8$ lb. Assuming the running of the condensate pump requires 8 hp., the efficiency of which is 70 per cent, we get $\frac{8 \times 2545}{0.7 \times 9800} = 2.92$ lb. of coal. Total, 132.73 lb. of coal. On the one hand we have 51.6 kw.-hr. and 4.92 lb. of coal. On the other hand 132.73 lb. of coal.

The significance of these figures for one year's run for plants having access to water power may be realized upon the following calculation, assuming coal cost at \$10 per 2,000 lb. and the price per kw.-yr. at \$30:

		Total Cost
a.	51.6 kw.-yr. @ \$30.....	\$1,548
	21.5 tons of coal @ \$10.....	215
		\$1,763
b.	580 tons of coal @ \$10.....	5,800
	Saving by a vs. b.....	\$4,037

Using coal to produce the electrical energy, the vapor compression evaporator will prove its superiority to a triple-effect apparatus where byproduct steam is not available. Assuming a large steam turbine power station 1 kw.-hr. may be obtained with 10 lb. of steam and we get:

a. Compression Evaporator:

$$\frac{51.6 \times 10}{8.5} = 60.8 \text{ lb. of coal to run the compressor.}$$

$$\text{Total: } \frac{4.92 \text{ lb. of coal for addition steam}}{65.72 \text{ lb. of coal}}$$

In other words, 33.6 lb. of water evaporated per lb. of coal.

b. 1. Triple effect evaporator:

$$2 \times 8.5 = 17 \text{ lb. of water evaporated per lb. of coal.}$$

2. Quadruple effect evaporator:

$$3 \times 8.5 = 25.5 \text{ lb. of water evaporated per lb. of coal.}$$

The new system is thus superior even to a quadruple effect evaporator. In other words, the coals might in this case be better utilized in a power station than in direct heating.

More important, however, is the case when coal is used to produce high-pressure steam utilized in a power station, the exhaust steam being used for heating purposes. In this case we may substitute the necessary power for the corresponding heat energy, the mechanical efficiency of the motor taken into account. The thermal losses in compression increase the heat of vapors and are utilized in the system.

1. For 2,200 lb. of water evaporated per hour and requiring 51.6 kw.-hr. we use:

$$\frac{51.6 \times 3420}{9800} = 18.2 \text{ lb. of coal}$$

$$4.95 \text{ lb. of coal}$$

$$\text{Total: } 23.15 \text{ lb. of coal}$$

This gives an evaporation of 95 lb. of water per lb. of coal, being a very high efficiency.

2. On the other hand, using a high-pressure quadruple-effect evaporator, the efficiency of which is 3 lb. of water evaporated per pound of steam, we have:

$$\frac{2200}{8.5 \times 3} = 86.5 \text{ lb. of coal minus about 442 lb. of}$$

exhaust steam, corresponding to $\frac{442}{8.5} = 51.8$ lb. of coal, the difference being 34.7 lb. of coal per 2,200 lb. of water evaporated, or $\frac{2200}{34.7} = 63.7$ lb. of water evaporated per pound of coal.

From these calculations it is seen that the vapor compression system of evaporation is an economical one. In addition it has the advantage that the boiling point of the liquor may be regulated as is best in each particular case, although the high-pressure steam status is utilized, the evaporators running either under vacuum or high pressure.

It might be emphasized that all calculations given herewith are based upon the investigations by Prof. Stodola and are performed with a small installation. At greater capacities the efficiency of the compression should be greatly increased. Evaporating 2,200 lb. of water per hour, the efficiency was shown to be 19.3 lb. per kw.-hr., but having a capacity of 40,000 lb. per hour, the efficiency has proved to be 59.2 lb. of water evaporated per kw.-hr. As a matter of fact, dealing with solutions similar to water, the efficiency has proved to be 84 lb.

The construction of the vapor compression system evaporator may be varied according to the cost of the available electrical energy so as to get the most economical operation. Power being cheap, the compression may be high in order to decrease the heating surfaces. On the other hand, with high-priced electricity, it is possible to diminish the necessary power by using evaporators having larger heating surfaces.

Dr. C. L. Alsberg Director of Stanford University Food Research Institute

DESPITE the fact that an adequate food supply for armies and for civilian populations always has been recognized as one of the vital factors in war, the Allied nations and the United States plunged into the late struggle without a vestige of preparation in that particular. There were no data, either statistical or historical. The food administrators had to work under the greatest handicaps, because no one ever had studied or had gathered information as to mass feeding. When Herbert Hoover met with the Allied food administrators during the war they each agreed to do all possible toward securing a systematic study of this problem so that it might be available in case of another emergency. Millions had been spent in studying ordnance, tactics and transportation, but Germany was the only country which had given any attention to the equally important matter of using food resources in a way that would help win a war.

When the war was over Mr. Hoover did not forget his promise to the other food administrators. He found that there was no prospect for the Government to take up at that time a work of that character, so he went to the Carnegie Corporation and interested it in financing such an undertaking. Then he went to the trustees of Stanford University and secured their promise of co-operation. As a result the Food Research Institute of Stanford University has been created and Dr. Carl Lucas Alsberg has been selected as one of its directors. There are to be two other directors. Pains-taking care is being taken in the selection of these men. Mr. Hoover regards the work as essential to the national defense as is the furnishing of munitions to the Army or fuel to the Navy. Armies travel on their bellies, and doubly so do the civilian populations which stand behind those armies. The excitement at the front may relegate to a secondary importance an irregular or an inadequate food supply. In a battle-swept area or in a center of mobilization all are aware of the difficulties attendant upon food supply and irregularities are discounted. Not so in industrial centers far from the fighting line. With nothing spectacular or exciting to vary the monotony of the day's drudgery, irregularities in food have even a more important bearing on morale.

To produce food in sufficient quantities and to distribute it in a manner insuring the maximum of effective use was one of the great war problems which

brought strikingly to the attention of the various nations the necessity for a study of the food problem as a whole. America is taking the initial step in this direction with the establishment of the Food Research Institute, none of the Allied countries having found the time as yet to start work along these lines. Holland, having seen the necessity, already has acted and has a study of this character well under headway.

The study in the United States is to be divided into three groups, each under the immediate charge of a director. One of the directors will be chosen for his qualifications to handle the economic and statistical features of the work. Another will supervise the activities pertaining to human nutrition, while the third will look after the industrial side of the question. It is this last angle of the work to which Dr. Alsberg

has been assigned. No announcement has been made as to those who are being considered for the remaining directorships.

The Carnegie Corporation has agreed to finance the work for a period of from seven to ten years. The scale on which it is to be undertaken will be determined after three years. Great care will be exercised not to duplicate either work or equipment. Very general co-operation with existing laboratories is expected.

Dr. Alsberg plans to continue his work as chief of the Bureau of Chemistry of the United States Department of Agriculture until July 1. It probably will be Oct. 1 before he will be able to give his full time to his new duties.

Dr. Alsberg was born in New York City April 2, 1877. He was prepared for college by tutors and at preparatory schools, and entered Columbia College in 1892, receiving his A.B. in

1896. He then entered the medical department of Columbia University and received the degree of M.D. in 1900. In the same year he received his A.M. from Columbia University. While studying medicine he devoted considerable time to research with Dr. P. A. Levene, now chief of the chemical department of the Rockefeller Institute for Medical Research. In 1900 he did advanced work at the University of Strassburg in physiological chemistry, medicine and pharmacology. Later he worked in Berlin with Emil Fischer.

Late in 1902 Dr. Alsberg was appointed assistant in physiological chemistry at the Harvard Medical School. In 1905 he was made the head of the department. In 1908 he resigned to accept the position of chemical biologist in charge of the poisonous plant laboratory of the Bureau of Plant Industry. On Dec. 16, 1912, he succeeded Dr. Harvey W. Wiley as Chief of the Bureau of Chemistry.

DR. CARL L. ALSBERG

Miscellaneous Alloys of Nickel

Principal Data on Binary Alloy Systems With Nickel as One Constituent — Use of Nickel in Bronzes and Light Aluminum Alloys—Composition and Electrical Characteristics of Many Special Resistance Alloys—Analyses of Complex Alloys for Various Minor Uses

By PAUL D. MERICA
Superintendent of Research, International Nickel Co.

EQUILIBRIUM OF BINARY ALLOYS OF NICKEL

THE constitution of most of the important binary alloy series with nickel has been investigated fairly completely and the principal results of the investigations of the systems forming one or more compounds are given in tabular form in Table I. It is observed that nickel has a strong tendency to form solid solutions with other metals, either of limited compositions or in all proportions. Structurally speaking, it is perhaps mainly for this reason that the metal forms a constituent of so many commercially useful ferrous and non-ferrous alloys. Thus nickel and any one of the following metals are soluble in all proportions in the solid state: Chromium, cobalt, copper, iron, manganese, palladium and platinum. A 60:40 nickel:chromium alloy has the minimum melting point of that series at 1,290 deg. C.; a 70:30 nickel:iron alloy melts at 1,425 deg. C., the minimum for that series, and correspondingly, a 44:56 nickel:manganese alloy melts at 1,000 deg. C.

Gold and nickel form a simple eutectiferous series; the eutectic analyzes 27 per cent Ni and melts at 950 deg. C., and is composed of two conjugate solid solutions containing approximately 16 per cent gold and 6 per cent nickel respectively.

Table II gives the principal data concerning three binary systems having limited solubility in the liquid state.

ACID-RESISTING ALLOYS

Many nickel alloys display an even greater resistance to acid corrosion than nickel itself. The acid-resisting properties of Monel metal have already been noted by the author in CHEMICAL AND METALLURGICAL ENGINEERING, vol. 24, p. 291 (Feb. 16, 1921). It may be re-

membered that Monel metal does not resist the action of nitric acid.

Chromium:nickel alloys are acid-resisting and are used for dipping baskets and other articles exposed to acid corrosion. The following results of tests communicated by the Driver-Harris Co. indicate the degree of

TABLE II. BINARY ALLOYS OF NICKEL HAVING LIMITED MISCIBILITY IN THE LIQUID STATE

eters, as it is practically unattacked by 25 per cent nitric acid. The alloy may be cast and machined, although with some difficulty; it has a tensile strength of about 50,000 lb. per sq.in.

Tungsten:nickel alloys have been prepared by Irmann² and their resistance to the action of sulphuric acid studied. He discovered that the resistance of nickel to the action of 65 per cent acid, which itself is considerable, is increased fourfold by the addition of 5 per cent of tungsten and twelvefold by the addition of 10 per cent. Alloys containing under 18 per cent have sufficient ductility that they may be formed into sheets.

Fairlie³ has reported some tests of nickel:lead alloys for acid-resisting purposes. Alloys containing from 1 to 3 per cent of nickel and remainder lead were more resistant to the action of 50 to 60 deg. Bé. sulphuric acid, both hot and cold, than pure lead, and had a tensile strength of about 3,000 lb. per sq.in., about 30 per cent greater than that of lead. The antimony:lead alloys were much harder and stronger and although resistant to the action of cold were not resistant to the action of hot acid.

Some of his results are reproduced in Table III.

TABLE III. ACID RESISTANCE OF NICKEL:LEAD ALLOYS

The disadvantages of the nickel:lead alloys are their low strength and difficulty of preparation, due to the great difference between the melting points of the components.

Clamer has patented ferronickel alloys for production on non-corrodible sheets, rods, etc. These contain approximately 25 to 50 per cent nickel, 5 to 20 per cent copper, remainder iron.

An alloy⁴ of 30 per cent tantalum and 70 per cent nickel is reported to be resistant to the action of boiling aqua regia. Siemens-Halske has patented similar compositions for this purpose.

NICKEL IN BRONZES

Nickel is used to some extent, particularly abroad, as a component of brasses⁵ and of aluminum bronzes, to which it appears to impart desirable properties. Parker⁶ has pointed out the desirability of studying the possibilities of these alloys for the construction of high-speed turbine blading for superheated steam, and mentions several compositions which are in commercial use in Great Britain. These are as follows:

	A	B	C
Copper.....	82.07	79.63	79.0
Aluminum.....	2.54	9.77	11.5
Nickel.....	14.64	4.13	5.0
Manganese.....	nil	0.94	nil
Zinc.....	0.68	nil	nil
Iron.....	trace	4.80	4.5
Silicon.....	0.04	0.14	

Bronzes of similar composition containing aluminum and nickel have also been produced commercially as substitutes for nickel silver under such names as aluminum silver and minargent. They have a fine white color and will take a good polish.

Read and Greaves⁷ have contributed results of extensive tests of aluminum:nickel bronzes of this type. These alloys were found to forge and roll satisfactorily and to have good mechanical properties, the hardness increasing with the nickel content. Table IV contains the results of some of their tensile tests on annealed

TABLE IV. TENSILE PROPERTIES OF NICKEL:ALUMINUM COPPER ALLOYS						
Chemical Composition			Tensile Properties			
Per Cent Cu	Per Cent Ni	Per Cent Al	Yield Point	Tensile Strength, Lb. per Sq.In.	Elongation in 2 In., per Cent	Reduction of Area, per Cent

alloys rolled from 2½-in. ingots. Corrosion tests in fresh and sea water carried out by these investigators indicated that the presence of nickel in aluminum bronzes decreases markedly the corrosion in sea water; it does not seem to affect corrosion in fresh water in any definite manner, as shown in Table V.

The properties of light aluminum alloys containing nickel have been studied by Read and Greaves⁷, Merica, Waltenberg and Finn⁸ and Merica and Karr,⁹ and it seems to have been demonstrated that nickel in aluminum up to 4 per cent will produce an alloy which will roll and work very readily and have quite satisfactory mechanical properties. Thus an alloy containing 3.9

TABLE V. CORROSION TESTS OF ROLLED AND ANNEALED NICKEL:ALUMINUM:COPPER ALLOYS					
Chemical Composition			Corrosion Loss in Weight in Lb. per Sq.Ft. per Month

94.04	0.92	5.04	0.00031	0.00008	
90.09	4.90	5.01	0.00012	0.00007	
85.08	10.07	4.85	0.00002	0.00012	

per cent of nickel in the form of rolled and annealed sheet possessed the following tensile properties:

Tensile strength.....	20,200 lb. per sq.in.
Elongation in 2 in.....	24 per cent

It does not appear that light alloys containing nickel are as strong, hard and resistant to corrosion as those which have been hardened with copper, manganese or zinc in similar amounts and would therefore not give much promise of replacing present commercial wrought light alloys of the copper:aluminum, copper:magnesium:aluminum or zinc:aluminum type.

Promising results have been obtained, however, with the addition of from 1 to 2 per cent of nickel in aluminum casting-alloys containing also from 2 to 3 per cent of copper, and there seem to be some possibilities of development in this direction. Thus Merica and Karr have obtained the following tensile test results with a

sand-cast alloy containing 3 per cent copper, 0.8 per cent manganese and 1.5 per cent nickel:

Tensile strength..... 24,000 to 25,000 lb. per sq.in.
Proportional limit..... 6,000 to 7,000 lb. per sq.in.
Elongation in 2 in..... 8.5 per cent

In this connection it might be noted that nickel is used in the casting alloy called magnalite, and in certain varieties of magnalium produced abroad; these will contain from 1 to 2 per cent of nickel.

Nickel has been substituted for a portion of the tin in government bronzes with attractive results (Burgess and Woodward¹⁰); these investigators give the following results of tensile tests of castings:

	Tensile Strength	Yield Point	Elonga- tion	Reduc- tion of Area
88 Cu, 5 Sn, 5 Ni, 2 Zn...	40,700	13,100	31.8	28.0
89 Cu, 4 Sn, 4 Ni, 3 Zn...	39,700	11,500	31.2	31.2

These results may be compared with advantage to the American Society for Testing Materials specifications for government bronze (88 Cu, 10 Sn, 2 Zn) as follows:

Tensile strength..... 30,000 lb. per sq. in.
Elongation in 2 in..... 14 per cent

The proposal has also been made by McKinney¹¹ to substitute nickel for a portion of the copper in 88:10:2 by using some cupronickel scrap in making the alloy.

ALLOYS FOR ELECTRICAL PURPOSES

The chief electrical uses for alloys containing nickel for the construction of pyrometer thermocouples and the construction of rheostats and electrical heating devices. The use of an alloy containing from 3 to 5 per

Zamium.....	60	bal. Cr, Mn, W.							A nickel-chromium alloy, resistant to corrosion.

cent manganese for sparkplug terminals has been mentioned. The characteristic which renders this group of nickel alloys of value for these purposes is their resistance to oxidation and alteration at the higher temperatures (up to 2,000 deg. F.) at which they are used, in conjunction with their high electrical resistivity, low temperature coefficient of electrical resistivity and either high or low thermal electromotive force against iron or copper.

The principal base metal thermocouples are copper against constantan, iron against constantan (Leeds and Northrup, Bristol, Brown pyrometers) and Chromel against alumel (the Hoskins thermocouple). The temperature-electromotive force relations of these three elements are given in Table VI, quoted from Foote, Harrison and Fairchild,¹² the values being average or standard ones. Adams¹³ has shown how to apply deviation curves based on one temperature-electromotive force measurement to lots of such wire having slightly different relations.

The alloys used for electrical heating and for the construction of rheostats or electrical resistances may be

divided into several groups: (1) The nickel:chromium alloys having a high electrical resistivity, low temperature coefficient together with maximum resistance to oxidation and alteration at higher temperatures; (2) the ferronickel alloys with lower resistivity and resistance to oxidation but considerably cheaper; (3) copper:nickel alloys having lower resistivity and inferior heat-resisting properties than the first class, but with practically negligible temperature coefficient of resistivity at ordinary temperatures, a very necessary property in the construction of precise electrical resistances for measuring instruments, and (4) the alloys similar to nickel silver, which are the oldest alloys used for electrical purposes and are being displaced by the others.

The compositions of alloys manufactured commercially today are listed in Table VII, together with approximate compositions and physical properties, principally as described by the manufacturers owning the patents. Most of these alloys are furnished in wire and in ribbon form and are manufactured by melting either in crucibles or electric furnace, pouring into small ingots which are first hot-rolled, annealed, and then cold-drawn with annealing into the finished form.

¹²Bulletin 153, Am. Inst. Mining Eng.

The alloy constantan, or copper:nickel, which also is sold under a number of trade names, is chiefly used for pyrometer and electrical resistance wire. It may be rolled at the temperatures (1,175 to 1,200 deg. C.) used for Monel metal and annealed at a slightly lower temperature—i.e., 850 deg. C. The tensile properties of copper:nickel alloys containing approximately 45 per cent of nickel will average as follows:

	$\frac{1}{4}$ -in. Hot-Rolled Wire Rod	Annealed Wire	Hard-Drawn Wire
Tensile strength, lb. per sq.in. . .	65-85,000	60,000 to 65,000	110,000 to 140,000
Elongation in 2 in., per cent.	25-40		

The general subject of electrical resistance has received much attention by Hunter and Sebast,¹³ and Sebast and Gray.¹⁴ An alloy of very high resistivity (113 microm-cm.) and of negligible temperature coefficient (0.000078 per deg. C.) was found containing 17 per cent chromium, 71 per cent nickel and 12 per cent copper which would appear to have commercial possibilities; it resists oxidation at higher temperatures to a remarkable degree and is easily manipulated in drawing. An alloy was found containing 48 per cent copper, 39 per cent nickel and 10 per cent manganese which has a resistivity of 70 microhm-cm. and zero temperature coefficient at 20 deg. C.; this is superior to manganin in its higher resistivity. The highest values of the resistivity were found in the binary nickel:manganese and nickel:chromium and in the ternary ferronickel:manganese, ferronickel:chromium and copper:nickel:chromium alloys. The ternary alloys have a higher value of the resistivity than the binary alloys. Alloys of low temperature coefficient were found chiefly among the copper:nickel:manganese alloys.

An interesting corollary of the development of electrical resistance alloys for rheostats and heaters has been that of heat-resisting alloys, and many compositions used at first because of their electrical- and heat- or high temperature-resisting properties are now used because of the latter alone. Nickel:chromium alloys in the form of castings are now much used for furnace muffles, carbonizing and annealing boxes and pyrometer protection tubes. These alloys (see Table VII) withstand very well the action of gas and oil flames as well as that of molten lead, cyanide or of carbonizing mixtures at temperatures up to 2,000 deg. F. (1,100 deg. C.).

MISCELLANEOUS ALLOYS

Besides its use as a principal alloying element in the well-known alloys just considered, nickel enters into the composition of a great variety of other commercial and experimental alloys, in which it acts perhaps principally to increase the hardness without an appreciable loss of ductility. However, it is also considered to exercise other functions. In Table VIII are assembled data on the chemical composition and use of a number of miscellaneous alloys in commercial use or mentioned in the literature which contain nickel; this table does not include alloys which have been listed in former tables covering nickel:silver alloys and those for electrical purposes.

Nickel is a powerful decolorizing agent for metals such as copper and gold. Several jewelers' white alloys are produced today as substitutes for platinum under the name of white gold; they contain from 20 to 50 per cent of nickel, with the remainder gold.

An alloy of 90 per cent nickel and 10 per cent tin is used to some extent for valve seats and rings.

Nickel in small amounts has been found to exert a beneficial effect on copper:lead-bearing bronzes in preventing the segregation of the lead. Thus, a much-used railway bearing bronze for heavy bearings contains:

	Per Cent		Per Cent
Copper.....	64	Lead.....	30
Tin.....	5	Nickel.....	1

An alloy of nickel and zirconium called Cooperite (see Table VIII) after its discoverer has been patented for machine tools and appears to have shown some very interesting test results in comparison with ordinary high-speed steel.

Legal Notes

BY WELLINGTON GUSTIN

General Rules of Water Purification Board of Rhode Island Do Not Aggrieve Corporations or Persons

Appeals of the Standard Oil Co. of New York and the Mexican Petroleum Corporation from orders of the Board of Purification of Waters of the State of Rhode Island have been dismissed in the Rhode Island Supreme Court.

The board was established under an act to prohibit and regulate the pollution of waters of the state and thereafter made an order establishing certain rules and regulations to prevent the discharge or escape of any petroleum, gasoline, kerosene, tar, oil or any product or mixture thereof into the public waters, as it was empowered to do under section 8 of the act. The corporations claimed that they were aggrieved by this order and were entitled to appeal from such order to the Supreme Court. They set up about twenty grounds upon which they contended that the order was unlawful and unreasonable.

To illustrate these rules the second regulation is here stated: "(2) No person shall discharge, or cause, suffer or procure to be discharged, or cause or suffer to escape into any of the public waters of the state any petroleum, gasoline, kerosene, tar, oil, or any product or mixture thereof."

It was charged that such rule and regulation is unlawful because the escape of such products is prohibited irrespective of whether or not such escape causes pollution of the waters; that on the same ground it is unreasonable; and that it is unlawful and unreasonable on the further ground that the escape of the above-mentioned products is prohibited irrespective of the circumstances, reason or cause for the same.

PROPERTY RIGHTS DETERMINE RIGHT TO APPEAL

However, the court said the right to appeal from such order is given only to those who are aggrieved by the finding of an inferior tribunal, and the party is "aggrieved" where the judgment or decree operates on his rights of property or bears directly on his interest. Neither of the corporations had been made the subject of proceedings under the act, but they feared some act or omission in the future might be complained of under some provision of chapter 1,914, and that such provision as applied to the circumstances of a case which might arise would be unlawful or unreasonable.

¹³J. Am. Inst. Metals, vol. 11, p. 115 (1917).

¹⁴Trans., Am. Electrochem. Soc., vol. 29, p. 569 (1916).

However, the court pointed out that the law requires the board, after it finds any person polluting the water, to order such person to prevent such pollution, and section 7 of the act prohibits prosecution without an order finding a violation, and section 10 prohibits conviction except for violation of the order of the board. It said the adoption of rules of the board under the authority of section 8 does not affect any person's property, but such rules are admonitory in character, and therefore do not "aggrieve" any person so as to authorize an appeal therefrom.

There was a strong dissenting opinion filed.

Rule Laid Down Where Defendant May Examine Plaintiff Before Trial

In the case of R. M. Jones against the Union Guano Co., Jones appealed to the Supreme Court of North Carolina from an order of the Superior Court of Rockingham County permitting the company to proceed with an examination of plaintiff before trial.

This case is one of nineteen actions in the Rockingham Supreme Court by nineteen farmers against the Union Guano Co. for damages for alleged breach of warranty in certain fertilizers causing them losses in their crops. After the complaint in this case was filed, the defendant filed a petition to examine the plaintiffs to obtain information on which to file its answer. The plaintiffs were directed to appear for examination on April 19, 1920, on which date they filed an answer to the petition and order, and asked that the order be set aside. The trial judge directed that the defendant should proceed with the examination of the plaintiffs and Jones appealed, the eighteen cases to await and abide the decision in this case.

This proceeding for the examination of the opposite party before trial may be permitted to the plaintiffs to procure information to frame the complaint (116 N. C., 480). Or after answer is filed the plaintiff may cause the defendant to be examined to procure evidence (18 Am. State Rep., 893). And likewise the rule extends to the defendant so to examine the plaintiff. But the Supreme Court said this right does not lie where, as in this case, the grounds of action are fully set out in the complaint, and the defendant can deny the same, or if so disposed it may answer on information or belief.

CANNOT SPREAD DRAGNET FOR ADVERSARY

As to both parties to a suit the court said in the case of Bailey vs. Matthews (156 N. C., 78): "The law will not permit a party to spread a dragnet for his adversary in the suit, in order to gather facts upon which he may be sued; nor will he countenance any attempt, under the guise of a fair examination, to harass or to oppress his opponent. It is a very rare case that requires the exercise of this function of the court, and the order should not be made without careful consideration and scrutiny."

The complaint filed by Jones and his eighteen associates, the court said, was a clear, specific statement as to the purpose for which the fertilizer was bought and the constituent elements which it was represented to contain by the Guano company, and allegations of the falsity of such representations and of the damage. It was said that the defendant did not need any examination of the plaintiff to enable it to answer these allegations.

It was laid down as the rule that an application for

an order for an examination be under oath, stating facts showing the nature of the action, is such that the testimony desired is relevant and that the examination is material and necessary and the information desired is not already accessible and that the application is made honestly and in good faith, and not maliciously. These requirements had not been met, the court said.

Guarantee of Product by Another Is a Direct Obligation and Need Not Be in Writing

In a recent case the proposition of guaranty was considered by the Supreme Court of California. It appears that the Simons Brick Co. employed the Interstate Vaccine Co. to vaccinate hogs with anti-cholera serum on the personal warranty or guarantee of one Wiglesworth that such vaccination would render the hogs immune from cholera, and that he would pay for any hog vaccinated which subsequently died. Afterward the Simons Brick Co. brought action against Wiglesworth and recovered judgment for \$5,637.20. Two questions were presented on appeal from this judgment. The first was as to whether there was a contract, and the second was as to whether such contract, if it did exist, was one which had to be in writing under the statute of frauds.

In passing on the question the court said that defendant's statement, that if the Brick company would employ a particular company and its product he would personally warrant or guarantee the results, was a proposal which had to be accepted within such time as the parties contemplated it would remain open, and, in the absence of express understanding, within such time as they reasonably had in mind under the circumstances. The facts showed that the offer of warranty was to remain open and that the employment of the company some months afterward was on an understanding of which the guaranty was a part.

NOT EVERY GUARANTEE MUST BE IN WRITING

As to the point made that the promise of guarantee was not in writing, the court said not every promise which may be aptly termed a "guarantee" is required to be in writing. It is only where the guarantee is a promise to answer for the debt, default or miscarriage of another that it must be in writing under the universal statute of frauds.

The question presented is: Was the promise of defendant one to answer for the obligation of another? The only other for which it could be considered that he intended to assume responsibility was the serum manufacturer. But it was not shown that any obligation of guaranty existed on the part of the manufacturer. There being no contract of warranty between the plaintiff and the manufacturer, the law implies a warranty or agreement that reasonable skill and care will be exercised in the selection and application of the vaccine, but that is all, nor were there any facts in the case from which an express warranty could be inferred between them. Since no warranty as sued upon existed between plaintiff and the manufacturer of the product, the agreement of defendant to pay for any hogs vaccinated which subsequently died was not a contract to answer for the debt or default of another—all of such contracts being required to be in writing under the statute of frauds. Such a guarantee of a product is a direct and separate contract, obligating the guarantor alone, and is enforceable, although not in writing.

GENERAL VIEW OF REICHSLAND PLANT

The Alsatian Potash Industry

Location and Extent of Alsatian Sylvinite Deposits—Physical Characteristics—Mining Methods—Surface Treatment: Crushing and Refining—Status of the Mines Before and After the War—Improved Operating Methods—Distribution of Products

By HENRI VIGNERON

Consulting Engineer, Société Commerciale des Potasses d'Alsace.

AS FAR back as 1869 borings were made in the vicinity of Mulhouse in search of petroleum and oil. Only the presence of common salt was discovered. More recently, in 1904, other searches were made; the first borings, near Wittelsheim, showed common salt at a depth of 1,100 ft. At a depth of 1,900 ft. the first layer of potash was found, and a second layer at a depth of 1,950 ft. It is interesting to note that the presence of potash would probably not have been discovered had it not been for the curiosity of Joseph Vogt, Sr., an Alsatian, who, noticing the red color of the salts, had them analyzed.

EXTENT OF THE DEPOSITS

Encouraged by the results, a company was formed to determine the limits of the basin. One hundred and sixty-five borings were made, varying from 750 to 3,000 ft. in depth. These proved the existence of a very large deposit of potash salts (sylvinite) over an area of about 68 square miles. It was also shown that there were two layers, or strata, of potash; the top layer containing a high percentage salt, 20 to 25 per cent K_2O , the lower layer containing potash salts varying from 15 to 18 per cent K_2O . The limits of the basin and the upper and lower deposits are shown on the map, Fig. 1.

During the war the battle front was very near the mines. L'Hartmannswillerkopf, or "Old Armand," that mountain of the Vosges where the "Blue Devils" (Alpins Chasseurs) resisted the attacks of the German army for three years, is only two miles from the shafts of the mine Marie-Louise.

The French did not destroy the mines, as they believed they would be restored to France some day; therefore the Germans continued to operate them with-

in range of the French guns. Unfortunately, when the French took possession of Alsace they found that the enemy, in retreating, had left the mines in a deplorable condition. All the shafts in process of construction were flooded. Those mines that were in active exploitation were left in such a state that it took many

FIG. 1. LOCATION OF ALSATIAN POTASH DEPOSITS

months and great expense to put them in working order. In spite of the difficulties, notwithstanding labor troubles and depression among workmen due to under-nutrition, in spite of the absence of a technical personnel, the reconstruction of the mines was immediately commenced. Since that time, thanks to the unceasing work of the French engineers, the Alsatian mines have

FIG. 2. SECTION ALONG AXIS OF DEPOSITS

reached a production power which the reader will be able to appreciate from the following discussion. It has already been stated that the deposit consists of two layers. These differ in grade and are about 60 ft. apart. The upper layer, 3.8 ft. in thickness, contains from 35 to 40 per cent of potassium chloride, or 22 to 25 per cent K_2O . This layer is found at a depth of 1,500 ft. at Amelie, 1,650 ft. at Theodore, 1,900 ft. at Alex, 2,500 ft. at Ensisheim. The lower layer is 7.5 ft. in thickness at Reichsland; 13.5 ft. at the mines Marie and Marie-Louise, and 16 ft. at the mine Amelie. Its nature varies from 23.5 to 32 per cent KCl , or 15 to 20 per cent K_2O .

The borings, which were made at various points, prove that the basin assumes the form of an ellipse, the axis of which passes through Ensisheim, running northeast to southwest. The northern end of this ellipse is prolonged by an additional strip which extends as far as Oberentzen. The western boundaries are formed by the Vosges and Harz Mountains, where the strata become thinner.

A cross-section (Fig. 2) following the axis of the ellipse as indicated by the dot-and-dash line in Fig. 1, shows that the deposit of potash salts, at a depth of 550 ft. at Reinigen, sinks to approximately 1,900 ft. at Ensisheim, only to rise again later.

The average analysis of Alsatian potash salts is as follows:

	Crushed Sylvinites, 14 to 16 per Cent	Raw Salts Rich Sylvinites, 20 to 22 per Cent	Refined Salts KCl, 50 to 60 per Cent	Refined Salts KCl, 60 to 62 per Cent
K_2O	14-16	20-22	50-60	60-62
KCl	21-25	32-35	79-95	95-98
$NaCl$	55-67	50-55	4-5	4-0.7
$MgCl_2$	0.1-0.7	0.1-0.5	0.1-0.5	0.05-0.1
$MgSO_4$	none	none	none	none
$CaSO_4$	2-5	2-4	0.3-0.4	0.1-0.3
H_2O	0.7-1.2	0.5-1.2	0.3-1.5	0.1-0.3
Insoluble:				
Clay, Fe_2O_3 ..	10-14	9-12	0.5-5	trace

Fig. 3 shows the cross-section of the shaft Theodore, which is situated in the center of the basin at Wittensheim. The shafts are from 15 to 18 ft. in diameter. At the opening, the casing, which continues to a depth of about 300 ft., is of cast iron and from this level to the bottom the shaft is lined with a casing of concrete from 1 to 1½ ft. in thickness.

The following table gives the composition of the successive layers encountered in sinking the shafts:

Strata	Depth m.	Thickness m.	Depth ft.	Thickness ft.
Soil	0	0.3	0	1
Sand and gravel	0.30	21.95	1	72
Fossiliferous blue clay	22.25	58.57	73	193
Gray, brown and blue clay	81	60.5	266	198
Rock salt with alternate clay strata	141.5	404.3	464	1327
Upper sylvinitic deposit	545.8	1.25	1791	4
Slate, etc.	547.05	18.0	1795	59
Lower sylvinitic deposit	565.05	4.10	1854	13
Rock salt	569.15	6.85	1867	23
Slate	576	4	1890	

PHYSICAL CHARACTERISTICS OF THE POTASH BEDS

In the descent into one of the potash mines nothing can be seen of the deposits passed in the shaft, because they are covered by the concrete lining of the shaft, or, near the top, by a metal collar. The first sight of any of the underground deposits is obtained as one steps from the mine cage into the mine workings. Here broad entries, well lighted by electricity, have been excavated in the thicker of the two potash beds. The galleries branch in various directions and are closed here and there by doors (brattices), which are needed to direct the circulation of the air that is forced through the mine for ventilation. Figs. 4 to 7 are typical views of the mine workings.

The sight of the potash salts in place is striking. High walls of sparkling crystalline salts are banded in approximately horizontal stripes of red and white, more or less wavy, giving the impression of a portion of

FIG. 3. STRATA AT SHAFT THEODORE

an immense flag. (See Fig. 7.) On clean mine faces the colors are beautifully clear. Some of the bands are a deep, rusty red or brick red. Other portions are delicately pink, and there is much white and gray granular crystalline material. The belief that the red and some of the pink salts are directly associated with the richer potash portions of the bed is so generally expressed throughout the field that it must have some foundation in fact, although perfectly white or transparent crystals of almost pure potassium chloride have been found. Examination in detail shows that the coarse crystals, both red and white, are much intermixed, and it is not usually possible to trace a distinct boundary

TYPICAL VIEWS OF THE MINE WORKINGS

Fig. 4. One of the main galleries.
Fig. 6. Loading cars at the end of a gallery.

Fig. 5. Drilling at the end of a gallery.
Fig. 7. Present method of mining.

between them, but in general aspect the banding is very distinct.

The top and bottom of the potash beds, where the salts rest against adjacent clay or shale seams, are very clearly defined. The shale leaves a very clean surface in the roof of the mine, marked by some irregular pits or patches, but usually breaking clean from the salts. This is also true of the clearly defined shale seams that occur within the potash bed.

The two beds preserve their individual characteristics, including general thickness and relation to each other, as well as details of the shale partings and chemical character of the constituent members, with remarkable constancy throughout the field. The upper bed, containing a richer grade than the lower bed, is the thinner.

MINING METHODS

The room-and-pillar method of mining was employed by the Germans. Long parallel evacuation galleries from 475 to 650 ft. in length and from 140 to 200 ft. in width were used to remove salt from the minor galleries. The large wall separating these parallel galleries was removed during the process of mining. Inasmuch as no shoring or timbering was used, pillars or columns 6 ft. square and 12 ft. apart were left as supports. A map or plan of the galleries gives one the impression of a large checkerboard. These pillars were too weak to support the great weight of the roof and very often would break under the enormous overhead pressure. The Germans tried to reinforce them, filling in spaces with hollow wooden columns, the centers of which were filled with common salt (the waste byprod-

uct obtained in the manufacture of muriate). This method gave no security either against cave-ins, which frequently occurred without warning, or against fire-damp, caused by the bituminous slate forming the roof of the strata.

Electric and compressed air drills are used, and from 500 to 600 g. of explosive materials are required for each ton of crude salt extracted. The temperature in the galleries is about 95 deg. F., but the ventilation system employed reduces this to a temperature of about 80 deg. in the working galleries.

SURFACE TREATMENT

Some idea of the extent and arrangement of the crushing and refining plants can be gained from Figs. 8 to 10. The salts are brought to the surface by electric or steam hoists (Fig. 11). Rotary dumps (Fig. 12) discharge the contents of the cars into storage bins. From these the salts pass to a jaw crusher, where the coarser lumps are broken to about the size of a man's fist, and the material is then spread on a revolving table, where it is sorted hurriedly by one or several workers, who remove the larger lumps of waste that happen to come to the surface with the rest. From this table it is fed to a lower level into grinding mills, which are of several types. From these the material either passes into storage for shipment as crude salts or goes into the refinery. The arrangement of the crushing machinery is shown in Fig. 13.

If the material is to be refined, it is elevated and passed through a screen. The fines, relatively cleaner and purer, go directly to boiling vats, and the coarse material, which includes more shale, is returned to the

mills for regrinding. It is then transferred, usually by belt, into hoppers, from which at intervals it is fed into boiling vats fitted with agitators.

REFINING

The refining is based on the difference in solubility of the mixture of chloride of potassium and chloride of sodium in hot or in cold water. As shown by the solubility curves, Fig. 14, one hundred c.c. of water can dissolve:

	KCl	NaCl
	g.	g.
at 100 deg. C.....	35.9	25.7
at 10 deg. C.....	12.5	29

A warm saturated solution of potassium chloride and of sodium chloride deposits 23.4 g. of potassium chloride on cooling, but as the solution is not saturated in sodium chloride this latter does not precipitate. Actually, due to loss by evaporation, a little of the sodium chloride is also precipitated.

The raw salts are heated with mother liquor derived from previous crystallizations, at about 225 deg. F. The liquors and salts from these solution vats are discharged periodically, and the residue is drawn into draining vats which have perforated bottoms and revolving rakes, the latter assisting the draining of the residue while it is still hot (at about 195 deg. F.). When the free liquor is practically all run off, the residue is thrown out at the edge by means of the revolving rakes and goes to waste, usually being returned to the mine to fill old workings. The moist residue still contains several per cent of potash.

FIG. 8. GENERAL VIEW OF AMELIE MINE

FIG. 9. ANOTHER VIEW OF AMELIE MINE

The liquor then goes to settling vats, where it stays about fifteen minutes, beginning to crystallize on the surface almost at once. A long glass tube thrust into the solution, then closed at the top and withdrawn, shows the progress of settlement of the muddy slime, and a hinged drainage pipe is let down into the vat, so that its outlet end follows the rather distinct limit of the clear liquid. The mud and salt left in the bottom of the tank are again washed with hot mother liquor.

The liquor, which is still distinctly muddy and with a temperature of about 195 deg. F., is drawn from the settling tanks through troughs to a battery of iron crystallizing vats of the ordinary type (Fig. 15), where as it cools it deposits the crop of muriate (potassium chloride) of varying degrees of purity, the quantity and quality of the product obtained depending somewhat on the care with which the various steps of the process are conducted, the length of time allowed for crystallizing and the amount of chilling. After the mother liquor has stood for several days it is withdrawn and returned to the process. The crust that forms with each cooling is from 2 to 5 in. thick on the sides of the tanks and somewhat thicker at the bottom. The salt is dug out of the crystallizers by hand and loaded over the sides into tramcars, whence it is taken to a rotary drier, where any surplus moisture is removed before bagging.

The coal consumption is about 600 lb. for 1 ton of muriate of potash, and 3 tons of crude salts are used to produce 1 ton of muriate.

STATUS OF THE MINES DURING AND AFTER THE WAR

The following table gives the quantities of crude salts extracted from various mines during the war:

	1913 Tons	1914 Tons	1915 Tons	1916 Tons	1917 Tons	1918 Tons
Reichsland	15,103	38,847	41,364	50,335	81,787	79,674
Amelie I.....	137,876	53,335	14,434			3,290
Amelie II.....		30,550				
Max	35,656	23,048	2,250	37,086	43,378	34,818
Joseph	21,875	23,197				
Else	23,665	23,826				
Theodore	47,608	39,244	22,698	90,623	159,044	173,706
Prince Eugene ..	47,608	39,243	22,698			
Marie	9,634	15,143	5,457	12,910	4,344	27,151
Marie-Louise ...	7,080	15,143	5,457	13,220	27,701	
Alex	1,600	24,310		300	3,877	14,860
Rudolph	2,636					
Total	355,341	325,886	114,358	204,474	320,131	333,499

From this is noted the very large quantity extracted from the mines Theodore, Prince Eugene and Reichsland during the year 1917-1918. This intensive extraction left the galleries in such a deplorable condition

that it took many months' labor and much expense to get them in working order. The elevator of the Alex mine, which was undermined by water when the shaft was flooded, was repaired during the war by the German management, but it is only since the French regained possession of the mines that pumping out and reparation has been undertaken in the other flooded shafts. The shafts Marie and Else have been repaired. The shaft Rudolph has been pumped out, but about 600 ft. of masonry must be repaired and a new elevator installed. The shaft Ensisheim I has been pumped dry and entirely repaired. Sinking, which must go down to approximately 2,600 ft., has been continued. The shaft Ensisheim II is in a similar state. As soon as the shaft has been pumped dry, it is necessary to repair at once the concrete lining in order to prevent further seepage of water. Seepage commences in most of the mines, especially in Anna I, at about 600 ft. below the surface.

When one takes into consideration the wasteful methods employed by the Germans and the deplorable con-

FIG. 10. HEADFRAME AT AMELIE SHAFT

dition in which they left the mines, some conception can be obtained of the enormous difficulties encountered and successfully overcome by the French engineers.

It has been stated above that the Alsatian potash deposit consists of two layers: One from 9 to 12 ft. in thickness; the other from 3 to 4½ ft. in thickness, the latter lying only 60 ft. above the former. The Germans, with their usual lack of foresight and wasteful methods, commenced operations on the lower layer first, and inasmuch as no supports or timbering were

FIG. 11. STEAM HOISTING-ENGINE

used, this rendered exploitation of the upper layer very difficult, if not dangerous. In some parts this upper layer, which contains the richest salt, may be considered as lost.

In order to protect the shafts, the working galleries are begun only beyond a circle whose radius depends on the depth of the shaft, leaving shaft pillars which prevent the weakening of the strata surrounding the pits. Otherwise the concrete lining of the shafts would crack and break, rendering them unfit for future use. The Germans started their working galleries within a radius of 150 ft. Had this method been continued, cave-ins would have been inevitable and in a short time the mines would have been completely ruined. This practice has been stopped and measures have been taken to insure both the safety of the shafts and the machinery. Therefore the shaft pillars have been extended from 150 ft. to 600 ft. by French engineers.

PRECAUTIONS AGAINST FIREDAMP

The Germans were fully aware of the presence of firedamp, yet they did nothing to guard against this enemy of the miner. Firedamp in the potash mines comes from the slate beds located either in the roof or walls in the vicinity of the layer. It exudes from the slate beds only when the latter are reached by drilling or are dislocated by sinkings. Otherwise, the slate beds contain a very small amount of firedamp, since notwithstanding the experiments made with air currents in the old unembanked work, where the roof sinks by degrees, its presence is not revealed. Firedamp in the Alsatian mines is dangerous only when

FIG. 12. ROTARY DUMPS

sudden landslides occur in the parts worked by the room-and-pillar method. In this event the small amount contained in the slate is quickly freed and produces a sufficient amount of gas to form a flammable mixture with the surrounding air.

The principal precautions to be taken in the avoidance of accidents due to firedamp are known, and are as follows: The use of safety lamps; good ventilation; the suppression of instantaneous liberations of firedamp by use of modern mining methods.

None of these precautions was taken by the German exploiters. The lamps used were ordinary acetylene or flame lamps. The ventilation was the natural one created between the connecting shafts of each working. There were ventilators in some of the mines, but none were in working order. No preventive measures were taken against instantaneous emissions of firedamp. At the shafts Theodore and Marie-Louise the work was done by the room-and-pillar method, which left square pillars 12 to 15 ft. with unshored spaces.

At the shaft Amelie long chambers 15 to 19 ft. wide were worked, leaving 15 ft. of salt between the chambers. This pillar-and-chamber method was somewhat better than the one employed at the shafts Theodore and Marie-Louise, in the sense that the long walls are more resistant to cave-ins than the pillars, in that they allow only a slow sinking of the roof and a slow influx of firedamp. However, this method is no guarantee against sudden possible sinkings. In addition, 25 per cent of the salts at Theodore and Marie-Louise was lost by the use of this method, and 40 to 45 per cent at Amelie.

Various precautions have been adopted in order to lessen this danger of coal gas. Flame lamps have been

present time to prevent all sudden cave-ins and thus reduce to a minimum the dangers of firedamp. This will have, among other advantages, that of allowing the removal of all the salt, whereas by the German method, 25 to 50 per cent was lost. Thanks to the new arrangements of the galleries and improved ventilation, the work has been facilitated. In this manner, cave-ins of the roof of the galleries will be prevented. Nevertheless, the danger from firedamp is extremely small. There is no continuous emission of gas, as it is never detected in the air coming from the mine.

STORING EXPLOSIVES IN THE MINES

The removal of the salt is done by the use of explosives, generally compressed black powder. Since the

FIG. 14. SOLUBILITY CURVES

consumption for each ton of crude salt is a little over a pound, the total consumption for a shaft which has a daily output of 500 tons will be from 550 to 600 lb. Thus it is necessary to have a large quantity of explosives in the mine proper. Fulminate of mercury detonators are used, and these are very sensitive to shock.

The Germans, regardless of the danger to life as well as to the safety of the mines, stored large quantities of explosives and detonators together. The correct procedure is to distribute the explosives to the miners in separate rooms far from the main storerooms, so that if an explosion occurs during the handling of the cartridges, it will not be communicated to the whole supply. At present, detonators are in separate rooms and the distribution rooms are at some distance from the supply rooms.

WEIGHING APPARATUS

It is absolutely necessary that in a plant which sells only a fraction of its product in the crude state and

FIG. 13. CRUSHING AND GRINDING MACHINERY

replaced by safety lamps. The new directors, who were formerly directors of coal mines, use natural ventilation, which, by a system of deflectors or doors, forces the air through all the working galleries. These are used wherever they were formerly installed. The possibility of the formation of firedamp has been lessened by abandoning the room-and-pillar method of mining and by using instead the pillar-and-chamber method in those parts where bracing is still impossible.

Another method of mining is being tried at the

FIG. 15. CRYSTALLIZING TANKS

the remainder as refined, there should be weighing apparatus in order to know exactly the quantity delivered to the plant, and therefore to know exactly the yield. The Germans had no scales and there were weighing machines for the cars only, and no attempt was made to increase production.

DIFFICULTIES OVERCOME BY NEW MANAGEMENT

Other instances of the peculiarities in the German methods of working the mines are: The exaggerated length of the research galleries, which run in directions without any rhyme or reason; the floor level of the main galleries is irregular; in the mine Amelie, for example, the width of the tracks is not the same for the two communicating parts of the mine, so that the cars of one part cannot go to the other shaft.

All these numerous errors committed by the Germans imperiled not only the future of the mines but also constituted a permanent danger to the safety of the miners. In all cases the less important mistakes only occasioned heavy operating expenses and prevented the mines from reaching their highest state of development. These errors are so numerous that one is led to believe that they were made intentionally to hinder the future development of the basin.

It is not only these obstacles that the French have overcome but it is also necessary to repair and install new machinery, mobilize an entirely new and efficient executive staff, capable of meeting all conditions and of rendering, by modern methods, a highly developed organization, capable of supplying the potash needs of the entire world.

FACILITIES FOR DISTRIBUTION OF PRODUCTS

Alsace-Lorraine has ample transportation facilities to insure quick delivery to all parts of the work, either by water or by rail. When the Rhine is navigable, the potash is shipped by rail to Strasbourg, where it is loaded on barges which proceed directly to Antwerp, at which point it is loaded on steamers. When the Rhine is too low to permit navigation, the potash is shipped directly from the Alsatian mines to Dunkirk or Antwerp, and from there by steamer to the various markets of the world.

In order to facilitate the sale and distribution of Alsatian potash salts, the Société Commerciale des Potasses d'Alsace was formed with one end in view—i.e., giving service and satisfaction to its buyers in order to come into more direct touch and intimate relations with the largest market of the world, namely, the American. As an indication of ability to supply the American market, the following tonnages are announced as available for export to the United States between May 1, 1921, and March 31, 1922:

	Tons	K ₂ O Tons
Kainite (sylvinite), 14 per cent.	420,000	60,000
Manure salts (rich sylvinite), 20 per cent.	500,000	100,000
Muriate of potash, 50 per cent.	100,000	50,000
High grade muriate of potash, 60 per cent.	12,000	6,000
	1,032,000	216,000

For sales purposes, the lower grades are referred to as kainite and manure salts because these terms have become firmly established in the trade.

The Société has recently opened its United States bureau in New York at 25 West 43rd St. The object of this bureau is to come into direct touch with the American fertilizer manufacturer and to increase the good feeling which has always existed in the past between the American consumer and the Alsatian potash industry.

Some Synthetic Resins From Furfural

BY GERALD H. MAINS AND MAX PHILLIPS

A PRACTICAL method for the cheap production of furfural, 2-furfuraldehyde, $C_5H_4O_2CHO$, has recently been developed in the Bureau of Chemistry,¹ and furfural promises to become one of the cheap organic chemicals. Relatively few commercial uses have as yet been developed for this product, and the bureau is now carrying on an investigation for the development and extension of this field. The present paper is a preliminary report on one phase of the work.

RESULTS REPORTED IN THE LITERATURE

That furfural reacts with various compounds, especially phenols and amines, to form products of a tarry or resinous character more or less indefinite in composition has long been recognized in the literature.² The scarcity and very high cost of furfural made these reactions, however, of very little importance. During the past four or five years furfural has been produced on a small scale in France from wood and kapok waste. The recent work of Roger Adams at the University of Illinois,³ and of LaForge,⁴ Monroe⁵ and the authors at this bureau has further demonstrated the practicability of securing in this country furfural in large quantities and at a reasonable cost from corncobs. Thus the possibility of producing synthetic resins from furfural is brought within the realm of economic importance.

A good foundation has been laid for the study of the formation of the hard or infusible type of resin by the condensation of furfural with phenols in the rather extensive investigation of Beckmann and Dehn.⁶ Meunier⁷ has made some resins of the soft, fusible and soluble type by the action of furfural with sodium hydroxide, ammonia, acetone and aniline. The present paper will be limited to a consideration of this latter type, which is suitable as a varnish resin. We have made a more extended study of the conditions under which the resins described by Meunier are formed, and have studied the formation of soluble resins by the condensation of furfural with a number of other compounds.

EXPERIMENTAL

The method of attack was to determine first the optimum concentrations of amine (or other compound under test) and furfural for the formation of a resin at room temperature, approximately 25 deg. C. Five-gram portions of furfural were used and from one-fifth to three times that weight of the other compound. Where no resins at all were obtainable at room temperature the optimum concentrations were determined at 100 deg. C. Using the concentrations which gave the best results in the previous experiments, resins were made at certain readily obtainable laboratory temperatures: room temperature, 25 deg. C.; the temperature of boiling water, 100 deg. C., and that of a paraffine

¹The work on the production of furfural was suggested by Dr. F. B. La Forge of this bureau, and is an outgrowth of the general corncob utilization project which he is developing. Cf. *J. Ind. Eng. Chem.*, vol. 10, p. 925 (1918), *Chem. Age*, vol. 28, p. 332 (1920).

⁷George Meunier, *Mat. Grasses*, vol. 9, p. 4,516 (1916).

bath, 150 to 200 deg. C. Having determined the optimum temperature, the length of time necessary under the given conditions to form the most satisfactory resin was similarly investigated.

It might appear that the temperature could have been more finely adjusted than in our experiments, but in view of the fact that the resins are not pure compounds, but products of an indefinite and varying composition, and that the same consistency of resin can be produced over a rather broad range of temperature by varying the length of heating period, it was felt that in this work we should hold to certain readily obtainable temperatures and let the time be the variant. Our criterion of the quality of the resin was simply that it should be hard and fairly brittle when cooled to room temperature and yet not noticeably carbonized.

In some cases no resins were formed without the addition of a catalyst. Beckmann and Dehn⁸ used hydrochloric acid as a catalyst in their work on making infusible resins by condensation of furfural with phenols. We have found that hydrochloric acid is an exceedingly effective catalyst in producing resins from furfural. It not only effectively catalyzes the formation of both fusible and infusible types of resins from furfural and other compounds, but added to furfural alone causes the formation of an infusible resin. Its salts are also catalysts, but not quite as effective.

The results obtained with each compound follow, the reactions being carried on in an open flask unless otherwise stated, and all proportions being given by weight.

CONDENSATION WITH AMINES

Aniline. Equal parts of furfural and aniline heated for one hour at 200 deg. C. in an open flask or for three hours at 170 deg. C. in a flask attached to a reflux condenser give a black resin, hard and brittle at 25 deg. C.

Aniline Hydrochloride. Equal parts of furfural and aniline hydrochloride heated at 100 deg. C. for one hour produce a black resin, hard and brittle at 25 deg. C.

Aniline plus Hydrochloric Acid. Five parts each of furfural and aniline and one part of concentrated hydrochloric acid, sp.gr. 1.19, give a resin similar in characteristics to the above in ten minutes at 90 deg. C.

m-Nitraniline. By heating one part of furfural and two parts of *m*-nitraniline at 150 deg. C. for one hour and fifteen minutes a black resin becoming hard and brittle at 25 deg. C. may be obtained. If the temperature exceeds 175 deg. C. a violent reaction occurs giving off voluminous clouds of dense brown smoke.

Cymidine plus Hydrochloric Acid. Five parts of furfural, five parts of cymidine (1-CH₃,2-NH₂,4-isopropyl benzene) and one part of hydrochloric acid (sp.gr. 1.19) heated at 150 deg. C. for ten minutes give a dark reddish brown resin very hard and brittle at 25 deg. C. Without the presence of hydrochloric acid no resin is formed even after heating for three hours at 200 deg. C.

α-Naphthylamine. When heated for three hours at 200 deg. C. one part furfural and two parts α-naphthylamine condense to form a black resin, hard and brittle at 25 deg. C.

β-Naphthylamine. One part of furfural and two parts of β-naphthylamine mixed at room temperature, 25 deg. C., give the immediate formation of a reddish-brown hard, brittle resin.

o-Toluidine plus Hydrochloric Acid. By heating five

parts of furfural, ten parts of *o*-toluidine and one part of hydrochloric acid (sp.gr. 1.19), for one hour at 150 deg. C., a black resin is produced which is very hard and brittle at 25 deg. C. Without the addition of the hydrochloric acid no appreciable thickening of the liquid is found even after heating for three hours at 200 deg. C.

p-Toluidine. One part of furfural and two parts of *p*-toluidine heated for two and one-half hours at 150 deg. C. produce a black resin becoming hard and brittle when cooled at 25 deg. C.

m-Toluylenediamine. Equal parts of furfural and *m*-toluylenediamine, upon standing over night at room temperature, 25 deg. C., give a dark brown, hard, brittle resin.

Xylidine plus Hydrochloric Acid. By heating five parts of furfural, five parts of xylidine (crude mixed) and one part of hydrochloric acid (sp.gr. 1.19) together for fifteen minutes at 150 deg. C., a very thick, dark red, almost black, resin is formed, very hard and brittle at 25 deg. C.

Other Amines. No resins were formed by the action of furfural on amylamine, dimethylaniline, diphenylamine and *m*-phenylenediamine even after heating at 200 deg. C. for three hours. Furfural condensed with the following at room temperature to form crystalline compounds: *p*-nitraniline, benzidine and toluidine.

CONDENSATION WITH KETONES

Acetone plus Sodium Hydroxide. One part of furfural, one part of acetone and two parts of 50 per cent sodium hydroxide solution when heated in flask attached to a reflux condenser for thirty minutes at 100 deg. C. condense to give a dark brown solid mass. By washing out the excess alkali with dilute acid, drying at 100 deg. C. and cooling to room temperature a hard, brittle, brown resin is formed.

Methyl Ethyl Ketone plus Sodium Hydroxide. Five parts of furfural, two parts of methyl ethyl ketone and five parts of 50 per cent sodium hydroxide solution give almost immediately at room temperature, 25 deg. C., a dark brown gum. By washing out the excess alkali with dilute acid, drying at 100 deg. C. and cooling to room temperature, a hard brown resin is obtained.

MISCELLANEOUS CONDENSATION REAGENTS

Ammonium Hydroxide (Furfuramide Resin). To an aqueous solution of furfural an excess of ammonium hydroxide is added. The furfuramide formed, partially dried and heated for one hour at 100 deg. C., gives a reddish brown resin hard at room temperature.

Sodium Hydroxide followed by Hydrochloric Acid. One part of furfural and seven parts by weight of a 25 per cent sodium hydroxide solution are heated together for one hour in a flask attached to a reflux condenser. Concentrated hydrochloric acid (sp.gr. 1.19) is then added in excess and a black resin is formed, the excess of acid is washed out and a medium hard tar is formed which gradually becomes brittle upon standing.⁹

GENERAL PROPERTIES OF RESINS PRODUCED

The resins do not have sharp fusion points, softening gradually till fluid. The softening temperature of the resins made as described lie between 25 and 100

⁹The conditions for forming this resin are satisfactory only within a narrow range. If more dilute acid than the above is used a poor resin or none at all is formed. If the excess hydrochloric acid is not thoroughly removed the resin will change to the insoluble and infusible type.

deg. C., but have not been carefully determined, since the softening point can be raised to almost any reasonable temperature desired by simply heating the resins at higher temperatures or for a longer period of time.

All of the above resins are practically insoluble in water. They are somewhat soluble in turpentine, quite soluble in benzene, acetone and alcohol, and very soluble in furfural. The acetone, benzene and furfural solutions of these resins form varnish stains which when applied to wood give shades ranging from golden brown to black, depending upon the resin, the concentration of the solution and the number of coats applied. The surfaces thus coated have a glossy appearance.

APPLICATIONS

Of the furfural resins described those which are produced from cheap enough materials to be of possible practical importance at the present time are: furfur-aniline, furfur- α -naphthylamine, furfur-*o*-toluidine, furfur-xylylidine, furfur-acetone, furfur-methyl ethyl ketone, furfur-amide, and furfur-sodium hydroxide resins.

The appearance of the varnish stains on white oak when the resins are applied in a single coat from the saturated benzene and furfural solutions is given in Table I.

TABLE I. APPEARANCE OF FURFURAL VARNISH STAINS ON WHITE OAK

Resin	Shades Given by One Coat of Resin	
	Applied in Saturated Benzene Solution	Applied in Saturated Furfural Solution
Furfur-aniline.....	Light brown	Dark brown
Furfur- α -naphthylamine.....	Dark brown	Nearly black
Furfur- <i>o</i> -toluidine.....	Medium brown	Dark brown
Furfur-xylylidine.....	Dark reddish brown	Dark reddish brown
Furfur-acetone.....	Golden brown	Dark brown
Furfur-methyl ethyl ketone....	Golden brown	Golden brown
Furfur-amide.....	Reddish brown	Reddish brown
Furfur-sodium hydroxide.....	Medium brown	Dark brown

By allowing the furfural solutions to evaporate somewhat and applying several coats, furfur-aniline, furfur- α -naphthylamine, furfur-*o*-toluidine and furfur-xylylidine resins give beautiful black enamels. The furfur-sodium hydroxide resin also gives a black enamel, not quite as good as the others.

The resins are all derived from furfural, and furfural is an excellent solvent for them. The source of furfural, corncobs, is practically unlimited, and with a large demand the price will be very low.¹⁰

CONCLUSIONS

With the improvement by the Bureau of Chemistry of the processes for the production of furfural cheaply and on a large scale, resins made from it become of economic importance. The optimum conditions for the production of fusible resins suitable for use in varnishes by the condensation of furfural with amines, ketones and other compounds are given. It is shown that eight of these resins—namely, furfur-aniline, furfur- α -naphthylamine, furfur-*o*-toluidine, furfur-xylylidine, furfur-acetone, furfur-methyl ethyl ketone, furfur-amide and furfur-sodium hydroxide resins—can be produced from cheap enough materials to be of practical importance under present conditions. The varnish stains given by these resins in benzene and furfural solutions and their appearance when applied to oak are described.

Color Laboratory,
U. S. Bureau of Chemistry,
Washington, D. C.

¹⁰Furfural was quoted in this country at \$65 per lb. in 1917, \$30 in July, 1920, \$20 in December, 1920, and \$10 in January, 1921, is being produced in this laboratory (even with a very small apparatus) at a cost of less than \$3 per lb., and we estimate can, on a large scale, be produced for less than 10c. per lb.

Synopsis of Recent Chemical & Metallurgical Literature

Growing Uses of Magnesium.—The late war has contributed to a better appreciation of the important properties of magnesium metal, and its industry is now growing steadily. Its most useful properties are the low specific gravity (1.75), the great affinity for oxygen, and the very high heat of combustion. These last two properties make it one of the best reducing agents in metallurgy. As a deoxidizing agent it is utilized for the purification of aluminum, copper, nickel, brasses, bronzes and alloys of copper and nickel. When introduced in a galvanized material it gives a thinner and more brilliant coating. It is to be expected that it will be used as a deoxidizer in the steel industry as soon as means are found to slow down the intensity of its oxidizing action.

The alloys of magnesium, especially the magnesium:aluminum alloys, are bound to be used more extensively, due to their being very light. During the war the Germans made extensive use of a 90Mg:10Al alloy known under the name of elektron. Alloys known as magnalium, with 30 per cent Mg, have their resistance greatly improved by mechanical work such as forging, hammering and drawing. Other important magnesium alloys are known under the names of zimalium and duralumin. The demand for light and at the same time resistant alloys in the aeronautics industry especially is growing fast.

The electric and thermic properties of magnesium are also very important. Its electric conductivity is about 30 per cent of that of copper and, taking its thermic conductivity as 100, that of aluminum and of iron would be respectively 86.5 and 9.8.

The Société d'Electrochimie et d'Electrometallurgie of Clavaux (Isère) is now working extensively on the development of the magnesium industry.—*J. du Four Electrique*, March 1, 1921, p. 23.

Dissolved Gases in Glass.—All varieties of glass, even at ordinary temperatures, are in the liquid state of aggregation. They are liquids which have been cooled through their normal crystallization interval so rapidly that there has not been time for crystallization ("devitrification") to occur. In principle any liquid can by supercooling be brought into the condition of a glass, but since it still remains a liquid, it should possess the characteristic properties of liquids, including the power to hold gases in a state of solution.

During the process of manufacturing glass, large quantities of gas, mainly carbon dioxide, oxygen and nitrogen, are evolved from the batch owing to reactions such as:

On cooling the glass these gases should remain in solution and glass in the finished state may therefore be expected to contain appreciable quantities of these dissolved gases. Since no data concerning the nature or amounts of such dissolved gases were available, experiments were undertaken by E. W. WASHBURN, F. F. FOOTITT and E. N. BUNTING. The preliminary results have been published in Bulletin 118 of the Engineering Experiment Station, University of Illinois.

The existence of dissolved gases was demonstrated by melting a piece of perfectly clean homogeneous glass under atmospheric pressure in a vacuum furnace connected through a valve to a large evacuated tank. When the temperature reached about 1,200 deg. C. the valve was opened quickly, thus causing a sudden drop of pressure within the furnace. On opening the furnace (after cooling) most of the glass was found outside the pot, standing above it in the form of a large white mass of foam about six times the size of the original piece.

By the use of specially designed apparatus, analyses were made of the gas content of three types of commercial glass:

A barium flint optical glass; a light flint bulb glass; a borosilicate laboratory glass. Carbon dioxide, oxygen and nitrogen were found in varying amounts, the total volume (measured under standard conditions) being from 0.2 to 2 times that of the glass itself.

Evolution of dissolved gas tends to occur in the form of bubbles or "seed" whenever the pressure on glass, while in the fluid state, is decreased. Such a condition is met with in cases where the glass is "gathered" by suction, as in the case of the Owens machine. If the glass when it reaches the gathering machine is supersaturated with dissolved gases, the operation of gathering will evidently result in the formation of seed, some of which will not disappear again when the suction is released.

Results thus far attained indicate that a vacuum furnace process for the manufacture of certain types of glass is entirely feasible on an industrial scale, and that it offers a number of pronounced advantages over current methods. It eliminates entirely the fining operation as ordinarily understood, materially reduces the high finishing temperatures required with some glasses, produces in all cases a product absolutely free from even the smallest seeds, and these results suggest the possibility of considerably increasing the yield of perfect glass. Its main field of usefulness will probably be in the manufacture of certain types of optical glasses and in the manufacture of glass for high-vacuum apparatus.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Ammonium Sulphate.—Ammoniacal gas from coke ovens is led through coolers to a gas exhauster followed by a tar extractor. From the tar extractor the gas, moist and cooled, passes into the cracker pipes of the first two of three saturator compartments, which are separated by partitions but provided with connecting ducts for the overflow and interchange of portions of the saturation bath. The moist gas gives up its ammonia with relatively limited formation of ammonium sulphate and without appreciable incrustation within the saturator or salting up of the cracker pipes through which the gas enters. The ammonia-freed gas is passed through an acid separator and a heater and is then returned to the third compartment of the saturator, where it supplies the heat required for evaporation and consequent deposition of ammonium sulphate from the saturation bath. By means of an elaborate system of pipes, valves and bypasses, the order of the three saturator compartments may be changed at will. Separation of tar and ammonia liquor and recovery of the latter by distillation are accomplished in the usual manner. (1,366,111; JOSEPH BECKER, of Pittsburgh, Pa., assignor to the Koppers Co.; Jan. 18, 1921.)

Diaphragm for Electrolytic White Lead Cell.—In carrying out the Harrington process for the electrolytic manufacture of white lead considerable difficulty was experienced in obtaining diaphragms possessing the necessary mechanical strength, durability and the proper degree of porosity. It was practically impossible to maintain a cell in uninterrupted operation for more than a few days. An improved diaphragm has been designed by ELMER A. SPERRY, of New York, which permits of continuous operation for many weeks. One method of making such a diaphragm is as follows: A piece of duck canvas of suitable size and preferably of comparatively fine weave is first freed of grease by treating it with a caustic solution. The fabric is then subjected to a strong sulphuric acid bath (1.750 sp.gr.) for a length of time depending on the osmotic and

impervious qualities desired, say 30 to 45 min. Excess acid is washed off and finally neutralized in a bath containing about 5 per cent of sodium or ammonium hydroxide. Such diaphragms swell when moist and tend to crack and tear when allowed to dry on frames. It is necessary therefore, that they be kept moist before and after they are mounted on the frames. The chief difficulty in accomplishing this is to prevent the drying of that portion of the diaphragm which is unsubmerged in the electrolyte. This area is best covered by strips of treated cloth large enough to dip in the electrolyte and sufficiently absorbent to draw up electrolyte by capillary action and thus keep the diaphragm moist. (1,368,227, assigned to Anaconda Lead Products Co.; Feb. 8, 1921.)

Ammonium Perchlorate Blasting Powder.—Ammonium perchlorate explosives of relatively low strength are desirable for use in many operations but, as ordinarily made, they cannot be used in wet work; they harden and set during storage, and they are relatively insensitive. ARTHUR LANGMEIER of Dover, N. J., has found that a coating of trinitrotoluene on the particles of ammonium perchlorate and sodium nitrate used in this class of explosives not only renders the powder waterproof but facilitates storage and makes it possible to explode the charge with a No. 6 standard detonator. It is essential that the trinitrotoluene should form a protective film and not be present simply as an ingredient of a mixture. The ammonium perchlorate and sodium nitrate are placed in a steam-jacketed crystallizing and agitating kettle maintained at a temperature above the melting point of trinitrotoluene. After adding the trinitrotoluene the mixture is cooled with constant agitation. A preferred composition is as follows: 20 per cent ammonium perchlorate coated with TNT; 49 per cent sodium nitrate coated with TNT; 20 per cent trinitrotoluene; 10 per cent sulphur; 1 per cent wood pulp. (1,367,608; assigned to Hercules Powder Co.; Feb. 8, 1921.)

Fused Silica.—Fused silica articles may be made by reducing silica to plasticity in an electric resistance furnace and then blowing the plastic mass into molds. However, at the temperature required for this purpose gas is given off from the carbon or graphite core. This gas diffuses through the plastic mass and the finished article is therefore not homogeneous. By surrounding the resistance core with a thin graphite tube somewhat larger than the core, a space is formed through which the gases may escape. The space between this thin tube and a larger two-part graphite jacket is filled with the silica to be fused. After current has been passed through the core for a sufficient time, a plastic cylinder of fused silica is formed. This is then removed from the furnace and placed in a mold. A graphite nozzle is inserted in the hole through the center of the mass and superheated steam admitted under pressure so as to cause the mass to take the shape of the molds. (1,368,990; JOHN SCHARL, of New York, assignor to General Ceramics Co.; Feb. 15, 1921.)

Coke-Oven Construction.—A more uniform coke is obtained in an oven constructed so that the distillate can be drawn off in the usual way until the peak temperature is reached and can then be drawn off in the opposite direction. Steam is also admitted during the latter phase of the operation and the upper parts of the coking chambers are interconnected. The vapors and gases in passing downwardly through the charge have a cooling effect on the hotter portions of the charge and a local circulation is induced which causes heat to pass from the hotter portions to the relatively cooler portions of the charge, thereby preventing over-coking in the hotter zones but accelerating the coking of the under-done portions of the charge in the cooler zones. In addition, the steam acts according to the water gas reaction (which is endothermic), thereby absorbing much heat which would otherwise effect over-coking. In order to insure an efficient reversal of flow a channel-forming rod is forced into the bottom of the chamber by the pusher and left there until the charge has hardened enough to permit of its withdrawal without disturbing the channel. (1,369,673; HEINRICH KOPPERS, of Essen-Ruhr, Germany, assignor to Koppers Development Corp.; Feb. 22, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Chemical Warfare Service Dinner

What is expected to be a highly representative gathering of those interested in chemical warfare will take place in Washington April 16 at the annual dinner of the Chemical Warfare Service. At this dinner it is expected that a chemical warfare association will be launched.

The program has been arranged so that the chemical, as well as the military, side of the service will be brought out. Brigadier-General William Mitchell, of the air service of the Army, will discuss plans and possibilities of aerial offenses against battleships, which involve the use of smoke screens and gases. Brigadier-General Amos A. Fries will present some of the problems with which the Chemical Warfare Service now is wrestling and will outline the present character of the work being done under his direction.

General Pershing and Admiral Sims have been invited to attend and to reply to toasts.

More than 1,000 invitations have been sent out. Every effort has been made to reach all former Chemical Warfare Service officers and all reserve officers attached to that service. Arrangements are in charge of Major F. R. Maddux, of General Fries' staff. The dinner is a subscription affair and will be held at the Army and Navy Club.

Federated American Engineering Societies Activities

Permanent headquarters of the Federated American Engineering Societies have been established in Washington. A desirable location has been secured on the third floor of 719 Fifteenth St., N. W. (National Savings and Trust Building). Sufficient space has been obtained to accommodate the staff of the F.A.E.S. and at the same time provide a large lounging room or conference room for those who may desire to use the headquarters as a meeting place. It will be the purpose of the headquarters at all times to render as much personal service as possible to engineers who visit Washington. A special plan will be developed to the end that engineers visiting Washington may be able to transact business with the minimum amount of effort on their part. Engineers, therefore, are asked to notify it of an intended visit to Washington so that arrangements may be made to care for them. The executive secretary, L. W. Wallace, will be permanently located in Washington in the near future.

There is great activity in a number of states regarding the licensing of engineers. The F.A.E.S. has in every instance taken a part in such legislation. It has made an effort to have a representative at every meeting. It is not the desire of the F.A.E.S. to initiate such legislation nor to urge its passage, but it does take the position that it desires to be instrumental so far as possible toward securing the passage of a bill that will not be detrimental to public interests and to the engineering profession.

A very careful study is being made by the Employment Service conducted under the auspices of the F.A.E.S. This study purposes determining what policies should be adopted that will enhance the value and usefulness of the service to the individual members of the member-societies. This report will be submitted to the executive board at its meeting on April 16.

WORK OF COMMITTEE ON ELIMINATION OF WASTE IN INDUSTRY PROGRESSING FAVORABLY

The work of the Committee on Elimination of Waste in Industry is progressing according to schedule. It is now assured that all the field work will be completed on or before April 15. The publication of the final report of the committee will be undertaken immediately upon the com-

pletion of the field work. A definite program has been evolved for this phase of the work. Since the field investigation is going according to schedule, it is expected that the final report will also do so. The report will be published some time in June. The findings of the committee thus far are very significant and it has every reason to believe that the publication of this report will create a great deal of interest. The finest of co-operation has been obtained from all agencies approached. This has greatly aided the committee in its work.

There is a large interest on the part of engineering societies that have not yet become affiliated with the F.A.E.S. In recent weeks two have joined—namely, the Boston Society of Civil Engineers and the Engineering Society of Milwaukee. There are a number of other societies that are either voting upon it at the present time or have it under consideration by the executive board. It is reasonably sure that a number of other societies will become affiliated with the F.A.E.S. before July 1, at which time the opportunity of coming in as a charter member will expire.

The next meeting of the executive board is to be held in Philadelphia on April 16. The executive board will be the guests of the Philadelphia Engineering Club and the sessions will be held at the Engineers Club. The club is making preparations to have a large and interesting attendance. There is to be a dinner at the Bellevue-Stratford on the evening of April 16 which is to be addressed by the president, Mr. Hoover. A very large attendance of engineers is being arranged for. It is expected that this will be one of the most important meetings that the board has ever held.

American Engineering Standards

About a year ago the American Engineering Standards Committee was organized, and much of the time and effort of the committee has since been spent in laying a basis for an extended program. Considerable progress has already been made in the unification of the more important standards and in overcoming the confusion that was being produced by the numerous organizations (more than 100) that hitherto published engineering standards without systematic co-operation among themselves.

The committee itself is composed of forty-seven members representing seventeen bodies or groups of bodies, including six national engineering societies, five governmental departments and thirteen national industrial associations. Its function is merely to see that each body or group concerned in a standard shall have opportunity to participate in its formulation, which is in the hands of a working committee, technically called a "sectional committee." Each sectional committee is organized by and under the leadership of one or more of the principal bodies interested, such bodies being known as "sponsors." Sponsorships have been arranged for thirty-eight projects which were under way by the beginning of 1921.

An important part of the committee's work relates to safety codes. On Dec. 8, 1920, at a conference at which more than 100 organizations were represented it was unanimously voted that a comprehensive program of safety codes should be undertaken, to be carried out under the auspices of the American Engineering Standards Committee, to insure proper co-ordination and elimination of overlap, etc. Active work is now in progress on twenty-four such codes including "Foundries," "Gases," "Paper and Pulp Mills," "Refrigeration," "Presses," with hearty co-operation among the state commissions, associations of insurance companies, national engineering societies, manufacturers' and industrial associations, labor and civic organizations and technical bureaus of the Federal Government.

Organization of Petroleum Section, A.C.S.

The organization of a Petroleum Section has been authorized by the officers of the American Chemical Society, and it is proposed to hold the initial meeting of this section at the general meeting of the Society at Rochester, April 26 to 29.

For the Rochester meeting Dr. Thomas G. Dolbridge, Atlantic Refining Co., Philadelphia, has been appointed chairman and Dr. W. A. Gruse, Mellon Institute, Pittsburgh, secretary.

The purposes which this organization is expected to fulfill may be expressed as follows:

(1) To enable chemists and technologists engaged in the petroleum, shale-oil and natural gas industries to meet and to correspond, and to accumulate trustworthy information regarding the geochemistry of petroleum, oil-shale and natural gas, the conversion of the raw materials into manufactured products, and the characteristics and usages of these products, together with their transport and storage.

(2) To promote the better education of persons desirous of becoming petroleum engineers, refinery engineers or hydrocarbon chemists, and to elevate the professional status of those employed in the industries mentioned by establishing a high standard of scientific and practical proficiency.

(3) To encourage hydrocarbon chemistry.

(4) To co-operate with the American Petroleum Institute and with the National Research Council, and to collaborate with the American Society for Testing Materials in its work on the standardization of bituminous and petroleum products.

Fifty chemists and chemical engineers actively engaged in the petroleum industry have pledged their support and co-operation, and fifteen papers on the chemistry of petroleum have been promised for the first meeting. At this meeting it is desired also to take up such questions as that of the degree and scope of the activities of the section, the form of co-operation with other technical and scientific societies, the exact name of the section, and other interesting points. If time permits, it is planned to hold an informal symposium on the problems of the petroleum and allied industries.

All persons who desire to become members of the section are requested to send their names to the secretary. A full attendance at this organization meeting is urged and the submission of papers is solicited.

The secretary will be glad to have any suggestions which this announcement may call forth.

Chemical Problems in Cottonseed Oil and Jelly Manufacture

Monday evening, April 4, before the Rochester Section of the American Chemical Society and guests, Donald Howe, chief chemist of the Beechnut Packing Co., gave a talk on cottonseed oil and its products.

The byproducts of the vast cotton industry enter into the manufacture of many and various materials and articles of common use, such as lacquers, soap, salad oil, celluloid, etc. As in most other industries, the last few years have seen attention turned to use of heretofore waste products. It has been largely through the work of the chemist that these waste products have been converted into useful and marketable materials, and very often, as in the case of the cotton industry, the byproducts have a money value nearly equal to the main product.

For many years salad oil meant only olive oil. With the increasing cost of this oil a search was made for a desirable substitute. At first there was a good deal of popular opposition to the use of anything but olive oil for salads. The nutritive value of both peanut and cottonseed oil is practically the same as for the more expensive olive oil, and as for the taste, as Mr. Howe said, you really cannot tell the difference.

Cotton is raised in the Southern States, where the climate is semi-tropical. After picking, the cotton is taken to the gin and the seeds are removed. The seeds are graded according to moisture and quality, the latter depending on the amount of decay, size and other points. The moisture

should be lower than 10 per cent, otherwise the seeds may ferment and spoil.

The seeds are cleaned and the hulls cracked just enough to break the hulls but not to crush the seed. They are then screened to remove the hulls. The meats are then taken to the presses, where the oil is removed from the seed. The material left after removing the oil is called oil cake, which is a desirable cattle feed, having a high protein and fat content. When oil cake was first tried as a cattle feed the thinnest, poorest looking cattle were fattened, meanwhile being periodically weighed, the occasion being marked by a parade to the village scales. This practical method was one of the most effective pieces of advertising.

The oil as it is pressed from the seed is neutralized and refined. It contains some stearine, a fat having a high melting point. This is easily removed by simply cooling the oil, and as stearine solidifies it can be filtered off. The oil is bleached by fuller's earth.

With the increasing cost of lard the industrial food chemists made every effort to find a less expensive desirable substitute. They turned to cottonseed oil, but to get the oil to a solid at ordinary temperature was the problem. This was finally accomplished by the use of nascent hydrogen, which will convert the oleic acid of the oil into stearic acid of the fat having a higher melting point and being a solid at ordinary temperatures. Nickel is used as a catalyst in the hydrogenation which solidifies the oil.

This lard substitute, coming under various trade names, is a desirable and satisfactory shortening agent for all kinds of cooking. It is also well to note that its food value is about the same as lard.

MANUFACTURE OF JELLY

Mr. Howe told something about commercial jelly making and its corresponding laboratory problems. It is only within a few years that jellies have been made on a commercial scale. The old family cook book gives directions to the effect that not more than six glasses should be made at one time to be certain of the best results. But the making of jelly has been commercialized, even as most other household duties have. Jelly is made from the juice of fruits boiled down with sugar. The ability of the fruit juice to "jell" is determined by the proper combination of pectin, acid in the fruit, and sugar. Pectin is a complex carbohydrate present in certain fruits, such as apples, currants, oranges and lemons, and when boiled is converted into pectic acid, which forms calcium pectate with the calcium salts always found in the fruit.

Pectic acid and calcium pectate set to a jelly when certain fruits are boiled with water and the juice allowed to cool. When certain fruits, such as strawberries, which contain very little pectin, are desired for jelly pectin must be added. So much water should not be added to fruits that it will be necessary to boil the juice for a long time, because the acid present will so change the pectin that it will lose its ability to "jell."

At the close of his talk Mr. Howe treated the Section to Beechnut molasses popcorn bars, salad dressing and jelly.

Harry A. Carpenter, chairman of the registration committee for the National Convention, received the registration fees of those present and announced that the badges would be given out at the next meeting.

Prof. Ernest J. Woodland, president of the Section, announced that the speaker for the next regular meeting, April 18, would be Dr. Alsberg, chief chemist of the United States Bureau of Chemistry.

Civil Service Examinations

Vacancies in the Chemical Warfare Service, Edgewood Arsenal, Edgewood, Md., will be filled from the following open competitive examinations announced recently by the Civil Service Commission:

Chemist, \$3,000 to \$5,000 a year. Apply on Form 2118.

Associate chemist, \$2,000 to \$3,000 a year. Apply on Form 2118.

Junior chemist, \$1,400 to \$2,000 a year. Apply on Form 1312.

Science News Agency Founded

The establishment of an organization for the purpose of familiarizing the general reading public with the progress of scientific research has been announced at the offices of the National Research Council.

The new organization, to be known as "Science Service," has been substantially endowed and is chartered as a non-profit-making corporation. Its control is vested in a board of trustees composed of ten scientists and five journalists. The National Academy of Sciences, the American Association for the Advancement of Science and the National Research Council each elects three trustees. The personnel of the first board of trustees is announced as follows:

A. A. Noyes, director of chemical research, California Institute of Technology, Pasadena; R. A. Millikan, professor of physics, University of Chicago; John C. Merriam, president of the Carnegie Institution of Washington; D. T. MacDougal, director of the Desert Laboratory of the Carnegie Institution of Washington, Tucson, Ariz.; George I. Moore, director of the Missouri Botanical Gardens, St. Louis; J. McKeen Cattell, editor of *Science*, Garrison, N. Y.; George E. Hale, director of the Mount Wilson Observatory, Pasadena, Cal.; Vernon Kellogg, secretary of the National Research Council, Washington; R. M. Yerkes, chairman of the Research Information Service, National Research Council, Washington; E. W. Scripps, Miramar, Cal.; R. P. Scripps, Cleveland, Ohio; W. E. Ritter, director of the Scripps Institution for Biological Research of the University of California, La Jolla, Cal.; William Allen White, editor of the *Gazette*, Emporia, Kan.; Chester H. Rowell, Berkeley, Cal.; Edwin F. Gay, editor of the *New York Evening Post*.

The charter of the new organization is a wide one, authorizing Science Service to employ newspapers, periodicals, books, lectures, conferences, motion pictures and any similar educational agencies in the distribution of scientific information.

Edwin E. Slosson, for twelve years professor of chemistry at the University of Wyoming, for seventeen years literary editor of the *Independent* and author of "Creative Chemistry," "Easy Lessons in Einstein" and other popular science works, is to be the editor of Science Service. The manager is to be Howard Wheeler, formerly editor of the *San Francisco Daily News*, Pacific Coast manager of the Newspaper Enterprise Association, managing editor of *Harper's Weekly* and for five years editor of *Everybody's Magazine*.

The policy of the Service is to be one of co-operation rather than competition with existing press associations, news agencies and syndicates. It will aim to supply accurate and interesting articles on all branches of science and technology at the lowest possible cost.

Offices have been opened in the National Research Council Building, 1701 Massachusetts Ave., Washington.

Chicago Chemists Club Annual Meeting

The members and friends of the Chicago Chemists Club gathered on the night of April 1 for the informal dinner, second annual business meeting and social evening at the quarters, 315 Plymouth Court. Besides being one of the many meetings which are doing so much to weld the professional men of Chicago through close personal friendships to the advancement of chemistry in this community, it was also the occasion of the second election of officers for the coming year.

The retiring president, dean and father of Chicago chemists, William Hoskins, gave a characteristic address on club affairs. He spoke about the quiet demonstration of the success of the club launched under difficulties over a year ago, touching briefly on the benefits of the weekly meetings and the momentum gathered over the period to be taken up and augmented by the incoming administration. The club in one short year has passed through the stage of infancy and grown to full young manhood. It must become more closely linked to the affairs of the community. While the membership is small, it is made up of professional men of the better type and the organization may well take a larger part in civic activities, to become eventually a power

for better conditions in the Chicago district. There is great hope for the future and the support of all is needed in upholding the hands of the new officers to this end.

Paul Nicholas Leech, who was termed "the keystone of the arch," was called upon to describe the excellent work he had carried forward as chairman of the arrangements committee. A large part of the development of the club's progress is directly attributable to the tireless activity of Dr. Leech.

Reports by Messrs. Dunlap and Kawin showed the club to be shipshape as regards finances.

The officers for the coming year were next elected. Otto Eisenschiml, popular among chemists for his straightforward character and original wit, was unanimously elected president. L. W. Spring and W. Lee Lewis were chosen for first and second vice-presidents respectively. Paul Van Cleef was the unanimous choice for secretary, and Glenn H. Picard for treasurer. Carl S. Miner and J. R. Powell, staunch supporters of the better things for chemists, were made trustees.

The social feature of the evening was a profusely illustrated talk by Dr. Arthur J. Cramp of the American Medical Association on "The Dunes of Northern Indiana." Having been a dune fan for the past fifteen years, his description of this most remarkable territory held the deepest interest of the audience. A sea of sand covered with vegetation varying in kind from the tropical to the northern flora, these dunes merit the study of scientists and nature lovers.

State-Owned Cement Plant in Dakota

South Dakota passed a law in 1919 authorizing a commission to survey the state for suitable raw materials for cement manufacture, and—in case it found that the state can successfully engage in the business—to locate, construct and operate a cement plant. A report to the Governor has recently been printed, signed by the commissioners, Paul E. Bellamy, W. J. Sharwood and C. M. Harrison, in which they note that the best and most acceptable cement materials are found in the Black Hills and that owing to cheap fuel and available water power cement can be manufactured at Rapid City and delivered to consumers in the state much cheaper than from any other point. A plant site and quarry land have accordingly been contracted for. On the basis of August, 1920, costs a plant of 2,000 bbl. daily capacity will cost approximately \$2,000,000, in which first-quality cement can be manufactured for \$1.48 per barrel, exclusive of interest on investment, amortization, and apparently of taxes and depreciation.

The commission's estimates follow:

Cost of shale quarry equipment	\$47,000
Cost of limestone quarry equipment.....	40,000
Cost of cement mill.....	1,570,000
Cost of 200,000 bags.....	70,000
Cost of repair parts carried in stock.....	50,000
Operating capital	223,000
Total	\$2,000,000

Daily operating costs:	
Stripping in quarries	None
Shale quarry	\$69.63
Limestone quarry.....	131.75
Mill operating*.....	2,462.14
Charge against bags.....	49.86
Repair parts	215.07
Interest on operating capital.....	36.61

Total operating cost.....	\$2,965.06
Cost per barrel, f.o.b. plant.....	\$1.48

*Electric power purchased at 1½c. per kw.-hr.

In December, 1920, the date of the report, the commission was of the opinion that there would be a 50 per cent underproduction of cement during the next five years, and in view of the fact that no cement plant exists within 175 miles of the state boundaries the building of roads and other structures will undoubtedly be badly hampered. On Nov. 1, 1919, the price of cement was from \$3 to \$5 per barrel; the average wholesale rate delivered at each county seat on the basis of 1 barrel per capita was \$3.53, without sacks. Adding the average freight rate to the above-itemized cost leads the commission to believe that a like service can be performed by a state-operated plant for \$2.38 per barrel. The latter figure includes depreciation, amortization and interest.

Lenroot Impressed at Edgewood

That the United States should maintain the lead it has obtained in the application of chemistry to war is the opinion of Senator Lenroot of Wisconsin. On returning from a recent visit to the Edgewood Arsenal Senator Lenroot made the following statement to the Washington correspondent of *CHEMICAL & METALLURGICAL ENGINEERING*:

"While chemical warfare is abhorrent to the minds of everyone, it ought to be realized that it constitutes a kind of warfare which cannot be insured against by treaty or other agreement. Its possibilities are limitless. It is absolutely necessary, as a matter of defense, that we not only keep abreast with other nations but that we stay in advance of them with respect to the use of chemicals in warfare. The best protection against such warfare is to be better prepared in its use than is any other nation. If we are thus prepared there probably never will be occasion to employ it.

"I was very much impressed with Edgewood Arsenal, especially with the laboratory and the work going on there. I shall favor the continuance of research and development work in this branch of the military service."

In addition, Senator Lenroot had the following to say about the Muscle Shoals development:

"I do not think anything should be done at Muscle Shoals for the next two or three years. I never have taken the position that we should adopt the policy of complete abandonment. It may be that when costs come down it would be well to take up the development again. If it is done, however, it should be only upon the assurance that it would be a good business proposition for the Government. As a military precaution I think the nitrate plants and the big steam power plant should be kept in standby condition. This can be done at comparatively little cost."

New Jersey Clay Workers Hold Dinner in Honor of Ceramic School Designers

As a result of a contest recently held for a suitable design for the new ceramic building to be erected at Rutgers College, New Brunswick, N. J., the New Jersey Clay Workers' Association and Eastern Section of the American Ceramic Society gave a dinner to all contestants at the New Packer House, Perth Amboy, N. J., on Friday evening, April 1.

The prize contest was carried out under the auspices of the National Terra Cotta Society, which offered \$300 in prizes for a suitable design for the facade of the new structure, divided into a first prize of \$200 and second prize of \$100. Fourteen persons entered the competition, the winners being E. W. Moell, Rocky Hill, N. J., and S. R. Audsley, Perth Amboy, both employees of the Atlantic Terra Cotta Co., who received the first and second prizes respectively.

Charles Howell Cook, president of the Cook Pottery Co., Trenton, N. J., acted as toastmaster at the dinner. The speeches dealt with the work connected with the new ceramic school building, for which a state appropriation has been secured, and the broad possibilities for development in the ceramic industry in the state. Among the speakers were: Abel Hansen, head of the Fords Porcelain Works, Perth Amboy; State Senator Thomas Brown; E. V. Eskesen, president New Jersey Terra Cotta Co.; Charles A. Bloomfield, head of the Bloomfield Clay Co.; George H. Brown, director department of ceramics, Rutgers College; Charles W. Crane, the Crossman Co., South Amboy; Roy H. Minton, General Ceramics Co.; Leslie Brown, Lenox, Inc.; D. P. Forst, Robertson Art Tile Co.; Andrew Faltz, Lambertville Pottery Co., and Charles T. H. Phillips, head of the Sneyd Enamelled Brick Co., Trenton.

Prince of Monaco to Receive Agassiz Medal

An address on his oceanic researches by the Prince of Monaco will be one of the features of the meeting of the National Academy of Sciences which will be held in Washington April 25 to 27. On that occasion the Prince is to receive the Alexander Agassiz medal. The only previous award of this prize was to Dr. Johan Hjort.

Domestic Potash Producers Discouraged

Despite the fact that there is reason to believe the Ways and Means Committee will approve an import duty of 50c. a unit on potash, representatives in Washington of the domestic potash industry take a gloomy view of the situation. As a result of the intense competition which has sprung up between the French and the Germans it now appears that 50c. a unit will not afford adequate protection.

In their efforts to capture the American market, representatives of the French and of the German producers are said to be making heavy concessions in price. This is especially the case when a five-year contract can be arranged. The French are now in a position to produce on a large scale. Despite the fact that stocks of potash in this country already are large, the French are continuing to build up their reserves here. German stocks have reached the point where little additional potash is being imported from that country.

It is believed that genuine competition between the Germans and French will continue as long as the French properties are under the direct control of the government. It now seems certain, it is stated, that the government will buy in the properties and then will lease them to private companies for operation. Once this takes place it is regarded as almost certain that the present ruinous type of competition will end, if there is not an understanding as to prices.

Dr. F. G. Hopkins to Receive Chandler Medal

At a meeting to be held in Havemeyer Hall, Columbia University, at 8:15 p.m. Monday, April 18, the Chandler Medal will be presented to Frederick Gowland Hopkins, F.R.C.P., F.R.S., F.I.C., F.C.S., professor of biological chemistry, Cambridge University, in order to recognize publicly his pioneer and very valuable work in the study of food accessories, such as vitamins. Dr. Hopkins will speak on "Newer Aspects of the Nutrition Problem."

Co-operative Work in Ceramics

Plans are being developed for intensive co-operative work between the Bureau of Mines and the Bureau of Standards, Washington, D. C., and the national brick and tile associations relative to investigations and experiments in the manufacture of burned clay building products. A fund is to be provided for carrying out the work, which for the most part will embody improved methods of production and the solution of fundamental problems encountered in this branch of manufacture. The associations interested in the movement include the Face Brick Manufacturers' Association, the American Common Brick Manufacturers' Association, the National Paving Brick Manufacturers' Association and the Hollow Building Tile Manufacturers' Association.

Book Reviews

RAPID METHODS FOR THE CHEMICAL ANALYSIS OF SPECIAL STEELS, STEEL-MAKING ALLOYS, THEIR ORES AND GRAPHITES. By *Charles Morris Johnson*, Ph.M., Chief Chemist of the Park Works of the Crucible Steel Co. of America. Third edition, revised and enlarged. xi + 552 pp. New York: John Wiley & Sons, Inc., 1920. Price \$6.

The new edition of this well-known text will be welcomed by all who are interested in the analysis of steel and steel-making materials. At the present time it is necessary for the steel analyst to be prepared to determine or guard against the interferences of about one-half of the elements of the periodic table. And who would say the end is yet? The present book provides for nearly all the probable cases of today. New material not found in either of the previous editions includes the analysis of chrome-vanadium and chromium steels; the complete analysis of tungsten ore;

tantalum and tungsten in ores, alloys and steels; arsenic in steel; zirconium in steel; the complete analysis of crude zirconia; oxygen and arsenic in copper; boron in iron; a new modification for the determination of phosphorus in the presence of vanadium using a faintly ammoniacal water solution of ammonium molybdate; the analysis of clays; a chapter on the micrographic examination of steel; notes on electrical laboratory furnaces and special refractories; the analysis of ferrocerium and cerium steel. A further addition of interest is the facsimile of the certificate of the new British standard chrome-vanadium steel and a comparison of the results on this steel from three American laboratories.

In addition to methods for analysis the book contains much information on the design and equipment of a steel-works laboratory and on grinding, sampling and the annealing and microscopic examination of steel. Tables of typical analyses of ores, slags, refractories and special alloys given throughout the book are convenient. The text is well illustrated.

There is a very noticeable opportunity to arrange the material given in this book according to some more simple or more evident scheme; the analytical methods arranged either on the basis of the elements being determined or according to the class of material being analyzed and the scattered portions on other subjects gathered together. While the author does not state that the methods described are confined to those in use at the Park Works of the Crucible Steel Co., yet it is so implied. Certainly in many instances references to recently published papers along lines related to the context are lacking—e.g., methods for oxygen in steel, nitrogen in steel, zirconium in steels and ores, electrometric methods. Complete details of the method for determining phosphorus in the presence of vanadium of pages 41 to 45 are needlessly duplicated in pages 318 to 323.

LOUIS JORDAN.

* * *

THE THERMIONIC VACUUM TUBE AND ITS APPLICATIONS. By *H. J. Van der Bijl*, M.A., Ph.D. 392 pp., illustrated. Price \$5. New York: McGraw-Hill Book Co.

The publication of this book fills a need, experienced for a number of years by those not specialists in the field of conduction of electricity through gases, of a complete treatise on the theory and use of the vacuum tube as an amplifier and a detector of high-frequency electric currents. Although the principles employed in the operation of the vacuum tube as a rectifier, detector or amplifier have been described in detail in several treatises on the conduction of electricity through gases, or on the principles of electric wave telegraphy and telephony, this is the first adequate work devoted exclusively to that subject.

The book contains ten chapters, the first three of which are devoted to an introductory account of the properties of electrons, and of the conditions for their dislodgment from the atoms of gases and vapors and from solid substances. Chapter IV, on the physics of the thermionic valve—i.e., the two-electrode vacuum tube—discusses the general characteristics of the valve, while the effect of gases present in the tube is described in Chapter V. The principles of the use of the valve as a rectifier of alternating currents is described in Chapter VI. Chapter VII, the longest in the book, is devoted to a full description of the characteristics of the three-electrode vacuum tube and of the principles upon which its use as an amplifier is based. The use of the tube as an oscillation generator in a circuit having inductance and capacity is described in Chapter VIII, and Chapter IX is devoted to a description of its use as a detector and modulator of high-frequency electromagnetic waves as employed in radio telegraphy and telephony. Chapter X describes some of the miscellaneous applications of the thermionic tube, such, for instance, as its use as an electro-static voltmeter and as an ionization manometer, etc.

To those wishing to acquire a thoroughgoing acquaintance with one of the most important recent practical developments in the field of electromagnetism, this book is recommended.

C. C. VAN NUYS.

Personal

H. W. BLANCHARD recently severed his relations with the chemical division of Procter & Gamble Co., Cincinnati, Ohio, and is now connected with the physics department of Purdue University, LaFayette, Ind.

HIPPOLYTE COPAUX, of the School of Industrial Physics and Chemistry of Paris; PIERRE LELAUDOUX, of the Tunisian Phosphate Co.; Dr. EUGENIO DONEGANI, of the Sicilian Sulphur Co., and GEORGES FLUSIN, of Grenoble, are in the United States making a study of the fertilizer situation.

Dr. COLIN G. FINK, organizer and for the past four years director of the research laboratories of the Chile Exploration Co., has resigned his post. Formerly Dr. Fink was in charge of research at the Edison Lamp Works, Harrison, N. J.

ALFRED N. FLINN, who was formerly with the Hydraulic Steel Co., Cleveland, Ohio, in the research department, has been reinstated as associate chemist at the Bureau of Standards, Washington, D. C., where previous to the past year he was engaged for nine years in the chemical testing of structural materials, but his present assignment is in chemical control of the manufacture of optical glass.

ARTHUR L. HALVORSEN, who has been connected with the Roessler & Hasslacher Chemical Co. for the past ten years as research chemist, resigned Jan. 1 to do consulting work in cyanide hydrometallurgy and industrial chemical research in general. He is located at 174 Water St., Perth Amboy, N. J.

Dr. DAVID R. MERRILL has resigned his position as research associate in the Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology, in order to accept a position in the research laboratory of the Union Oil Co. of California, Oleum, Cal.

Dr. R. F. RUTTAN, head of the department of chemistry at McGill University, has been administrative chairman of the Honorary Advisory Council for Scientific and Industrial Research in the absence of Dr. A. B. Macallum in the Orient.

HERVEY J. SKINNER, HERBERT L. SHERMAN and GUSTAVUS J. ESSELEN, JR., have associated themselves under the name of Skinner, Sherman & Esselen, Inc., and will act as consultants in matters pertaining to the application of chemistry and biology to industrial operations.

Obituary

EDMUND COGSWELL CONVERSE, president of the National Tube Co. at the time of its merger into the U. S. Steel Corporation and later a director of the corporation, died suddenly of a heart attack on April 4, while at a hotel in Pasadena, Cal., where he and his wife had been living since February. His home was in Greenwich, Conn.

Dr. ERNST J. LEDERLE, the founder of the Lederle Laboratories and the Lederle Antitoxin Laboratories, which are now merged into the firm of Lederle & Provost, died on March 7, at Goshen, N. Y. Dr. Lederle was health commissioner of New York City during two administrations.

ELIE MILLETT, inventor of the Millett core oven and founder of the Millett Brass Co., died in Springfield, Mass., on Sunday, March 21. The Millett core oven was designed primarily to protect workmen in foundries from the intense heat from the old ovens and to eliminate the waste of heat when the charging door was opened. Mr. Millett acted on the theory that it was possible to have two doors on an oven instead of one and that it was also possible so to arrange the grates that the cores could be heated without opening both doors at once.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, April 11, 1921.

One of the most hopeful signs noted in the week's chemical activities was the gradual removal of distressed spot stocks of many materials from weak second-hand holders. This condition is beginning to exert its influence in many quarters and while sellers are content to quote around lately prevailing levels, buyers are having a hard time purchasing special brand goods.

A few large producers reported some improvement in domestic trade. Although the increase was not very noticeable, there was more steadiness and expansion than at any time since the beginning of the year. It seems reasonable to assume that the quiet absorption of resale goods will eventually make itself felt in first-hand quarters. With any signs of real buying, the spot market will recover very easily. The dormant buying movement since last fall has created a very artificial condition where the short seller may encounter some difficulty with any noticeable revival.

Special standard brands of *caustic soda* were in demand and where inquiries were heard at former quotations, buyers experienced much difficulty in obtaining any round lots. Resale standard *bichromate of soda* showed an extremely firmer tendency on several occasions.

GENERAL CHEMICALS

The *acetic acid* market continued unsettled, although tending toward the stronger end. Producers have held their prices on a fairly firm basis at former levels. The low prices are still quoted nominally, but it is generally known that deliveries are greatly delayed. The resale market is practically devoid of supplies, although an occasional odd lot is sold at former resale price levels. Quotations from leading manufacturers are based on 2½@3c. per lb. for the 28 per cent and 10@11c. for the glacial. A reduction in some directions has brought *nitric acid* down to a price basis of 6½@7½c. per lb. for the 40 deg. and 7¼@8½c. for the 42 deg. Prices on *sulphuric acid*, 66 deg., in tank cars are quoted at \$19@\$20 per ton f.o.b. works. It is understood that with the present weakness of sulphur, a firm order would bring about price concessions. *Ammonium carbonate* prices in some quarters are quoted firm at 9½c. per lb. Offers elsewhere are heard as low as 7½c. for imported material. Demand has been exceedingly slow, so that there is no definite agreement between sellers.

The market on *ammonium chloride* continues in an unsettled state with spot stocks moderate in the absence of any noted demand. Importers are doubtful as to the future and domestic producers are still firm in their prices. Imported white granular is quoted at 7@7½c. per lb. as against 10@10½c. by domestic makers. Manufacturers of *ammonium sulphate* are holding their prices at \$2.90@\$3 per 100 lb. in bulk lots f.o.b. works. Spot material in distressed hands is quoted at \$2.75@\$2.90 per 100 lb. f.a.s. steamer, in double bags. Lack of demand has forced down prices to a decided extent. *Bleaching powder* has remained in the same unsettled position. Makers are quoting \$2.75 per 100 lb. f.o.b. works, while the spot resale market is quoted at \$2.50@\$2.60. Prices on *copperas* are lower with the bulk quoted at 75c. per 100 lb. f.o.b. works. Quotations range upward to \$1.25 per 100 lb., according to the package and delivery.

The *caustic potash* market is stagnant with resale offerings still heard at the former levels of 9½@10½c. per lb. for reshipped American material. Makers' prices are meaningless in the presence of heavy stocks of spot goods and the absence of demand. Domestic producers have reduced the price of *sodium chlorate* and are now offering at 8½c. per lb. for any quantity. Resale lots of *caustic soda* were generally quoted at \$3.65 per 100 lb. ex-store and \$3.75 f.a.s. Odd lots could possibly be purchased at \$3.60, but most sellers were not eager to quote as low as this level

on standard material. The absence of any large inquiries gave the market a tame appearance, although the undertone remained quite steady. It was said to be doubtful if more than odd lots of domestic light *soda ash* could be bought below \$1.95@\$2 per 100 lb. in single bags, spot N. Y. Imported material was offered at \$1.90 and sales were recorded at this figure. Barrels were well held at \$2.20@\$2.25 per 100 lb. Trading in general was quiet with offerings small. Dense ash was held at 10c. per 100 lb. above the level.

Bichromate of soda dealers maintained the spot market at 7½c. per lb. in most directions, although it was intimated that a few odd lots might be purchased down to 7½c. Offerings were not heavy, but there was still enough material on hand to take care of the prevailing inquiry. Consumers are apparently content to restrict their operations to actual wants only. Strength in copper metal has strengthened the market for *copper sulphate*. Leading producers have made no revision in prices, but the market looks firmer and there are indications that buyers are taking more interest. Demand for domestic use is moderate, but the insecticide trade has not covered and improvement in business is expected from this source of consumption. Standard 99 per cent large crystals are quoted by first hands at 5½c. per lb. in carlots and small crystals, 98½-99 per cent, at 5½c. Odd lots of miscellaneous brands are on the market in moderate supply at 5½c. per lb. and possibly lower on firm business.

The following is a comparative list of miscellaneous chemicals since 1914:

Article	1921	1918	1914
Acetone, lb.	\$0.13	\$0.34	\$0.10
Acetic acid, 100 lb.	1.75	6.50	1.50
Ammonia alum, lb.	0.04	0.08	0.01½
Potash alum, lb.	0.05½	0.11	
Ammonia carbonate, lb.	0.09	0.12	
Ammonia aqua, 26 deg., lb.	0.07	0.10	0.02
Ammonia sulphate, 100 lb.	2.75		2.50
Arsenic, white powder, lb.	0.08	0.11	0.03
Arsenic, red, lb.	0.12	0.47	0.05
Bleaching powder, lb.	0.02½	0.07	0.01½
Blue vitriol, lb.	0.05½	0.10	0.04½
Bichromate soda, lb.	0.07½	0.20	0.04½
Bichromate potash, lb.	0.12½	0.45	
Borax, lb.	0.06½	0.09	0.04
Caustic potash, 88-92%, lb.	0.09½	0.75	0.04
Carbon tetrachloride, lb.	0.10	0.70	
Chlorate Potash, lb.	0.08	0.35	0.07
Citric acid, lb.	0.47	0.95	0.54
Cream tartar, lb.	0.30	0.65	0.23
Cyanide soda, lb.	0.20	0.32	
Epsom salts, 100 lb.	2.25	3.50	0.75
Formaldehyde, lb.	0.15	0.22	0.08
Glycerine, C.P., lb.	0.17½	0.55	0.19
Lime acetate, lb.	0.01½	0.04	0.01½
Oxalic acid, lb.	0.16½	0.45	0.06
Phenol, lb.	0.11	0.40	0.07
Permanganate potash, lb.	0.35	2.00	0.08
Prussiate soda, lb.	0.12½	0.55	0.11
Prussiate potash, red, lb.	0.48	0.90	
Prussiate potash, yellow, lb.	0.26	2.25	0.12
Rochelle salt, lb.	0.27	0.47	0.16
Soda ash, 100 lb.	1.95	2.75	0.75
Soda, caustic, solid, 100 lb.	3.65	5.25	1.80
Sulphur flour, 100 lb.	2.25	3.25	2.00
Sal ammoniac, gran., lb.	0.07	0.25	0.06½
Tartaric acid, lb.	0.36	0.85	0.30

COAL-TAR PRODUCTS

Trading in the coal-tar products marked during the past week has shown a tendency to expand in some quarters, but although sales are more numerous, the business is of a very small character, for spot lots, with nothing in the way of future requirements being considered. Production has been generally curtailed and covers a majority of the items on the list. Resale stocks in warehouses are not believed to be large and those close to the heart of trading expressed the opinion that the turning point in the dullness of the market has been passed. Prices have been steadily reduced and labor is gradually drifting back to work at revised schedules. Reports of developments from textile centers are very encouraging and the industry looks forward to a radical improvement in the very near future.

Crude products are moving in better volume and the tone of the market is steady. *Benzene* and *toluene* are not expected to show any further easiness in prices, while on the other hand any material increase would create a tight market in a short time. *Napththalene* is in easy supply and prices vary according to seller, with the flake at 8@9c. per lb. and the ball at 9¼@10c.

Intermediates are showing a much steadier tendency with sellers not trying to push business and shading only on

firm orders. *Aniline oil*, *beta naphthol* and *paranitraniline* are steady, with prices unchanged during the past week. Supplies of *nitro benzene* are reported as easy in most directions and figures range from 12@15c. per lb. Consumers are showing little interest in the market and only a light routine movement is recorded. The volume of trading in *ortho nitrophenol* during the period was said to be at a minimum. Supplies are available in some quarters on the basis of 75@80c. per lb. The market for *para phenylenediamine* has been quite steady during the week and a moderate volume of trading has been transacted on the basis of \$1.95@\$2 per lb. There has been no improvement reported in the market for *toluene*. The demand has been very light and supplies are fairly easy. Prices quoted by producers range from 28@31c. per gal., depending on quantity, with second-hand offerings slightly under these figures. Resale stocks of *para nitraniline* have been pretty well cleaned out and while it may be possible to find an occasional odd lot as low as 85c. per lb. the market has practically passed to first hands at 95c.@\$1.05 per lb., according to quantity. Demand has been quite slow. Offers of *dimethylaniline* on spot are heard at 48@50c. per lb. from second hands, with producers quoting 50@60c. per lb. Business has been limited to small lots.

MISCELLANEOUS MATERIALS

As far as prices are concerned very little change was evident in the miscellaneous materials market outside of a slightly firmer feeling in mostly all quarters. The demand in general is as yet confined principally to limited lots, but it was noted that transactions were more frequent. Indications pointed to an early increase in activity. Spring operations in the paint field are being pushed and relief is in sight. *Barytes* held steady and practically unchanged. *Blanc fixe* changed hands quite freely, but mostly in small lots. *Litharge* remained in much the same position. *Zinc oxide* figures held steady in all quarters.

While there continued to be little in the way of large-lot trading in *barytes*, a regular demand is heard for moderate amounts and on the whole a better feeling pervades this market. Prices held steady in all quarters with little inclination noted to change. The prime white remains quoted at \$30@\$35 per ton. Offerings of *blanc fixe* were plentiful but not pressed and prices held steady. The general asking price is 4½c. per lb., but intimations were made that bids of 4½c. would most likely be accepted. Numerous small lot sales were reported by factors, while on large lots very little activity was recorded. A firm tone prevailed in the *litharge* market, although trading in general was limited and spot stocks plentiful. First hands quote firm at 8½c. per lb. as an inside figure. Leading producers of *zinc oxide* reported nothing new and stated that the same routine inquiry continued to be received. Prices remained firm at 8½@9½c. per lb. for the XX grade.

The Chicago Market

CHICAGO, April 8, 1921.

Business in heavy chemicals showed a decided improvement during the past week, most factors reporting an unusually large volume of small orders. It is evident that supplies in consumers' hands are getting low and that they will soon be back in the market again.

In general the list remained firm, the most notable exception being c.p. *glycerine*, which was reduced by refiners to 17c. per lb., bulk basis. This marks the lowest level reached in seven or eight years. There is some demand for *soda ash*, which is quoted at 2½@3c. in a small way. *Caustic soda* is firm, the ground being offered at 4½c. per lb. in barrels, and the solid at 4½c. in drums. The inquiry for *formaldehyde* is good, and a considerable volume of business is reported at 16@16½c. per lb. Sales of *ammonium chloride*, white gran., are few, and lower prices are expected. Quotations vary from 11½@12½c., depending upon the quantity and the seller. The demand for *aluminum sulphate*, iron free, is rather light and the material is offered freely at 3½@4c. per lb. A fair inquiry is noted for *carbon bisulphide*, the price remaining firm at 8@8½c. in single drum lots. *Carbon tetrachloride* is not moving as well and is offered at 11c., in the large drums.

The lower prices in the New York market on *lead acetate*, white crystals, have not been reflected here and local dealers continue to quote 15c. per lb. in casks. They report a good volume of business and show little tendency to shade present prices. There is a small quantity of *potassium bichromate* in the market at 16c., but better prices are obtainable on material for prompt shipment from the East. *Potassium permanganate* is lower, spot goods being offered at 45@50c. per lb. As this material is offered for prompt shipment from abroad at much lower prices, the movement is slow and is confined to small packages. *Sodium bichromate* is firmer, the best price heard being 9c.; while some holders are asking as high as 11c.

Prices on *acetic acid* are unchanged, the glacial being offered at \$11 per 100 lb. and the 28 per cent at 2¼@3c. The demand for *citric acid* has increased and prices are firm at 47@49c. per lb. *Sulphuric acid* is unchanged, and manufacturers continue to ask \$19@\$20 per ton for the 66 deg.

VEGETABLE OILS

Unusually quiet conditions continue to prevail in this branch of the trade, and there is little or no demand to speak of. Buyers are holding off and there is a strong feeling in some quarters that several of the items will go lower, regardless of the talk of better prices. *Coconut oil* is quiet, the prevailing quotations running from 10@10½c. per lb. for single barrels. There is a slightly better demand for *linseed oil*, and dealers are asking 67@69c. per gal. in lots of 1 to 5 bbl.

NAVAL STORES

In general this market is dull and the only feature worth mentioning is the advance in *turpentine*. While it is still possible to secure small lots in some quarters at 60c. per gal., most factors have advanced their prices to 62c. *Rosin* continues as dull as ever, with most buyers showing little or no interest and few sales being reported. The holders are asking around \$7.25 for the WG grade, but this price could probably be shaded with a firm order.

COAL-TAR PRODUCTS

Benzene prices are lower, the new level being 28c. per gal. in drums for the 90 per cent and 30c. for the 100 per cent. There are a few small sales reported, but the demand is still far from satisfactory. *Naphthalene flakes* are moving in a small way and prices have been maintained at 9@10c. per lb.

The Iron and Steel Market

PITTSBURGH, April 8, 1921.

The iron and steel market continues its uneventful career. There is perhaps a slight farther broadening in demand for steel products, through shipping instructions becoming somewhat more numerous, but the business is very largely in carload lots and shows how very modest the requirements of consumers are at this time. Part of the business received is in new orders, but a large part is in releases against orders previously suspended. Buyers are not covering their full requirements in all cases with these shipping instructions, there being many cases in which stocks on hand are simply being pieced out. The proper conclusion seems to be that the rate of actual consumption is in excess of the rate of producing and shipping, but it does not follow that the rate of consumption will continue after all the stocks in buyers' hands have been disposed of. There is the automobile industry, for instance, which is increasing in activity from week to week and is reducing its inventories, but the spring buying season for automobiles will be entirely over before the stocks are all liquidated, and the sale of automobiles may then decrease.

In recent weeks the steel industry has been disposed to look for an improvement in steel demand at some time in the future by there being a large increase in dwelling house construction, contingent upon revision of wage rates and working conditions in the building trades. Latest trends, however, suggest that possibly the so-called "housing shortage" will be solved in part by a decrease in the demand for houses as incomes are reduced or disappear, as families separated by the search for the highest paid job with the least work are reunited and as men go back to the farm.

Detroit shows a surplus of houses after ten years of a "housing shortage," while the latest count in Cleveland shows 2,100 unoccupied houses.

PRODUCTION

Pig-iron production is down to about 35 per cent of capacity, there having been a sharp further decrease in the past few weeks. Merchant furnace production is particularly low, but there is a question whether production of pig iron by steel works is not still in excess of the current consumption by the works, for an estimate commonly accepted in the trade is that the independent steel works are operating at about 20 per cent of capacity and the Steel Corporation at between 40 and 45 per cent, which would make a rate for the whole steel industry of about 30 per cent. Independent operations have not changed materially for several weeks, while the Steel Corporation's operations continue to decline, though at a much slower rate than in February and the early part of March. The corporation is still operating to a considerable extent upon orders and specifications received long ago. Its incoming business is largely in the form of releases against orders previously suspended, and thus the natural trend would be for the Steel Corporation's production to continue to decline until business in general revives. A rough guess would be that if production is now at about 30 per cent of capacity it will decline slightly more in the near future, then rising to a rate of 45 or 50 per cent late in the year. At some time in the future there will be, of course, reasonably full industrial activity, but on account of the 50 per cent increase in steel capacity that has occurred since 1914 it is not entirely certain that at that time there will be full activity for the steel industry as now constituted.

PRICES

There has been no material change in the independent market for steel products in the past week and no great change for several weeks. This steadiness may be due to the almost complete absence of inquiry for large lots, which would promise a fair operating rate for the mill or department that secured the order. The independents are getting simply small orders, which do not afford anything like an economical operation. In many cases there is less competition for a carload order than might be expected, because some mills do not have an operation scheduled for an early enough date to meet the requirements of the prospective buyer. The independent market on carload lots is quotable at 2c. for bars, 2.10c. for shapes and plates, 3.75c. for black sheets, 4.80c. for galvanized sheets and about \$4 a ton off the standard list for pipe.

The Steel Corporation exhibits no intention of modifying its prices in the near future, its adherence to the Industrial Board price schedule being accepted by the trade now as a more natural thing than the trade was assuming a few weeks ago. Predictions as to when the corporation will reduce its prices have practically disappeared. It may be helpful to recall that during almost the entire period of more than a twelvemonth during which the corporation held its prices down to the Industrial Board schedule while the independents were charging higher prices there was continuous expectation that the corporation would advance its prices.

PIG IRON AND COKE

Pig iron displays no activity, and prices remain quotable at \$25 for bessemer, malleable and foundry and \$23 for basic, f.o.b. valley furnaces. Nearly all the independent coke operators in the Connellsville region have reduced wages to the scale of Nov. 10, 1917, involving on an average somewhat more than 30 per cent reduction from the former scale, which is still in force by the H. C. Frick Coke Co., the coke subsidiary of the Steel Corporation. On the inquiry for 500 tons of coke a day to a furnace at Portsmouth, Ohio, mentioned a week ago, it is understood the sale was made at not over \$3.75, the delivery being over five or six weeks until the byproduct coking plant at Portsmouth can be got in operation. The \$3.75 price is regarded as a close one even with the reduced wages now in force and little if any further liquidation in coke is to be expected. Coke sold at \$18 to \$19 last summer.

Dimethylaniline..... lb.	.48 - .55
Dinitrobenzene..... lb.	.30 - .32
Dinitrochlorobenzene..... lb.	.25 - .30
Dinitronaphthalene..... lb.	.33 - .35
Dinitrophenol..... lb.	.40 - .45
Dinitrotoluene..... lb.	.25 - .27
Dip oil, 25%, tar acids, car lots, in drums..... gal.	.38 - .40
Diphenylamine..... lb.	.60 - .70
H-acid..... lb.	1.30 - 1.50
Meta-phenylenediamine..... lb.	1.20 - 1.25
Monochlorobenzene..... lb.	.14 - .16
Monoethylaniline..... lb.	1.90 - 2.00
Naphthalene crushed, in bbls. (250 lb.)..... lb.	.08 - .09
Naphthalene, flake..... lb.	.08 - .09
Naphthalene, balls..... lb.	.09 - .10
Naphthionic acid, crude..... lb.	.70 - .75
Nitrobenzene..... lb.	.12 - .15
Nitro-naphthalene..... lb.	.30 - .35
Nitro-toluene..... lb.	.16 - .18
Ortho-amidophenol..... lb.	3.20 - 3.75
Ortho-dichlor-benzene..... lb.	.15 - .20
Ortho-nitro-phenol..... lb.	.75 - .80
Ortho-nitro-toluene..... lb.	.17 - .20
Ortho-toluidine..... lb.	.25 - .30
Para-amidophenol, base..... lb.	1.90 - 2.00
Para-amidophenol, HCl..... lb.	2.10 - 2.20

Para-dichlorobenzene..... lb.	.15 - .20
Paranitroaniline..... lb.	.90 - 1.05
Para-nitrotoluene..... lb.	.90 - 1.05
Para-phenylenediamine..... lb.	1.95 - 2.00
Para-toluidine..... lb.	1.25 - 1.60
Phthalic anhydride..... lb.	.50 - .60
Phenol, U. S. P., drums (dest.), (240 lb.)..... lb.	.11 - .13
Pyridine..... gal.	2.00 - 3.50
Resorcinol, technical..... lb.	1.85 - 2.00
Resorcinol, pure..... lb.	2.30 - 2.50
Salicylic acid, tech., in bbls. (110 lb.)..... lb.	.22 - .23
Salicylic acid, U. S. P..... lb.	.24 - .26
Salol..... lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal..... gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal..... gal.	.14 - .16
Sulphanilic acid, crude..... lb.	.30 - .35
Tolidine..... lb.	1.35 - 1.45
Toluidine, mixed..... lb.	.40 - .45
Toluene, in tank cars..... gal.	.25 - .28
Toluene, in drums..... gal.	.28 - .31
Xylidines, drums, 100 gal..... lb.	.40 - .45
Xylene, pure, in drums..... gal.	.42 - .45
Xylene, pure, in tank cars..... gal.	.45 - .48
Xylene, commercial, in drums, 100 gal..... gal.	.33 - .35
Xylene, commercial, in tank cars..... gal.	.30 - .33

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark..... lb.	\$0.24 - \$0.26
Beeswax, refined, light..... lb.	.27 - .28
Beeswax, white pure..... lb.	.40 - .45
Carnauba, Florida..... lb.	.68 - .70
Carnauba, No. 2, North Country..... lb.	.30 - .32
Carnauba, No. 3, North Country..... lb.	.18 - .19
Japan..... lb.	.19 - .19
Montan, crude..... lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p..... lb.	.04 - .05
Paraffine waxes, crude, scale 124-126 m.p..... lb.	.03 - .04
Paraffine waxes, refined, 118-120 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 125 m.p..... lb.	.04 - .04
Paraffine waxes, refined, 128-130 m.p..... lb.	.05 - .06
Paraffine waxes, refined, 133-135 m.p..... lb.	.06 - .06
Paraffine waxes, refined, 135-137 m.p..... lb.	.06 - .06
Stearic acid, single pressed..... lb.	.11 - .11
Stearic acid, double pressed..... lb.	.11 - .11
Stearic acid, triple pressed..... lb.	.12 - .12

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr. 0.930-0.940..... gal.	\$1.70
Pine oil, pure, dest. dist..... gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035..... gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla..... gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990..... gal.	.75
Pine tar, ref., thin, sp.gr. 1.080-1.960..... gal.	.30
Turpentine, crude, sp. gr. 0.900-0.970..... gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990..... gal.	.37
Pinewood creosote, ref..... gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl..... 280 lb.	\$4.90
Rosin E-I..... 280 lb.	5.15
Rosin K-N..... 280 lb.	5.50
Rosin W. G.-W. W..... 280 lb.	6.00
Wood rosin, bbl..... 280 lb.	6.25
Spirits of turpentine..... gal.	.57
Wood turpentine, steam dist..... gal.	.56
Wood turpentine, dest. dist..... gal.	.55
Pine tar pitch, bbl..... 200 lb.	7.00
Tar, kiln burned, bbl. (500 lb.)..... bbl.	14.50
Retort tar, bbl..... 500 lb.	15.00
Rosin oil, first run..... gal.	.45
Rosin oil, second run..... gal.	.48
Rosin oil, third run..... gal.	.60

Solvents

73-76 deg., steel bbls. (85 lb.)..... gal.	\$0.41
70-72 deg., steel bbls. (85 lb.)..... gal.	.39
68-70 deg., steel bbls. (85 lb.)..... gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.)..... gal.	.30

Crude Rubber

Para-Upriver fine..... lb.	\$0.17 - \$0.18
Upriver coarse..... lb.	.11 - .12
Upriver caucho ball..... lb.	.14 - .14
Plantation—First latex crepe..... lb.	.18 - .18
Ribbed smoked sheets..... lb.	.16 - .16
Brown crepe, thin, clean..... lb.	.18 - .18
Amber crepe No. 1..... lb.	.20 - .20

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls..... lb.	\$0.08 - \$0.09
Castor oil, AA, in bbls..... lb.	.09 - .10
China wood oil, in bbls. (f.o.b. Pac. coast)..... lb.	.07 - .08
Cocoonut oil, Ceylon grade, in bbls..... lb.	.09 - .10
Cocoonut oil, Cochin grade, in bbls..... lb.	.10 - .10
Corn oil, crude, in bbls..... lb.	.08 - .08
Cottonseed oil, crude (f. o. b. mill)..... lb.	.04 - .04
Cottonseed oil, summer yellow..... lb.	.06 - .06
Cottonseed oil, winter yellow..... lb.	.06 - .06
Linseed oil, raw, car lots (domestic)..... gal.	.62 - .62
Linseed oil, raw, tank cars (domestic)..... gal.	.55 - .55
Linseed oil, in 5-bbl lots (domestic)..... gal.	.65 - .66

Olive oil, commercial.....	gal	\$1 90	\$2 50
Palm, Lagos.....	lb.	.07	.07½
Palm, Niger.....	lb.	.06	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.05½	.05½
Peanut oil, refined, in bbls.....	lb.	.10	.10½
Rapeseed oil, refined in bbls.....	gal.	1 05	1 10
Rapeseed oil, blown, in bbls.....	gal.	1 15	1 20
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07½	.07½
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04½	

FISH

Light pressed menhaden.....	gal.	\$0.45	\$0.47
Yellow bleached menhaden.....	gal.	.47	
White bleached menhaden.....	gal.	.49	
Blown menhaden.....	gal.	.84	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24 00	— 30 00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22 00	— 26 00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10 00	— 17 00
Barytes, floated, f.o.b. St. Louis.....	net ton	26 50	— 28 00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES—The All-In-One Mfg. Co., 504 Marsh-Strong Bldg., recently incorporated with a capital of \$1,000,000 to manufacture metal enameled bathroom fixtures, has plans under way for its proposed new plant on a 10-acre site at Slauson Ave. and Downey Rd., lately acquired. The plant will consist of a group of eight main buildings, including 1-story foundry, 200x200 ft.; 1-story casting cleaning building, 50x200 ft.; 3-story enameling plant, 75x200 ft.; 1-story assembling building, 75x200 ft.; 1-story pattern shop, 50x200 ft.; warehouse and shipping building, office building, employees' building and garage. The new plant will cost about \$350,000 with machinery. J. C. Peterson, Sacramento, Cal., vice-president of the company, will act as architect and engineer for the plant.

Delaware

MILFORD—The Valliant Fertilizer Co., Laurel, Del., has acquired the fertilizer manufacturing plant of William Pierce, Milford. Possession will be taken at once and plans are under way for enlargements, to include the installation of new machinery. Edward S. Valliant will be manager of the Milford works.

Illinois

ARGO—The Corn Products Refining Co. is reported to be planning for the early reopening of its local grinding works, recently closed temporarily. Since the first of the year the plant has been operating on a 4-day week basis. The works give employment to about 2,000 operatives.

CHICAGO—The American Magnesia Products Co., 106 North La Salle Street, is having plans prepared for extensions and improvements in its 2-story plant at 5726 Roosevelt Rd., to cost about \$50,000. Bids will soon be asked.

CHICAGO—The Liberty Raw Hide Mfg. Co., 1435 West Austin Ave., is having plans prepared for the erection of a 2-story addition to its plant, estimated to cost about \$12,000.

CHICAGO—C. F. Davis & Co., Inc., dealer in tin plate and sheet metals, is planning the erection of a new plant at 37th St. near Iron. The investment including lot, 132x135 ft., will be approximately \$65,000. There will be about 15,000 sq.ft. of floor space. The main offices of the company will be located in the new building. This company also has branch offices and warehouses in New York and Pittsburgh.

CHICAGO—The Illinois Brick Co. has purchased the 26 acres bounded by Sacramento, Lunt and California Aves. and Pratt Blvd. This property consists of a clay bank acquired with the intention of extending the company's plant at some future date.

Indiana

VINCENNES—A portion of the plant of the Indian Refining Co., manufacturer of oils, was destroyed by fire March 26, with loss reported at about \$150,000.

Kentucky

LOUISVILLE—The Louisville Soap Products is planning for the rebuilding of its plant destroyed by fire March 27, with loss estimated at \$270,000.

Maine

GREAT WORKS—The Penobscot Chemical Fibre Co. has completed the construction of a new digester building at its plant and plans to place the structure in service at an early date.

WATERVILLE—The Keyes Fibre Co., Fairfield Rd., has awarded a contract to the Horace Purington Co., 178 Main St. for the construction of three additions to its plant, consisting of a 2-story machine and pump department, 45x95 ft.; 1-story pulp works, 40x150 ft.; and 1-story drier building, 90x140 ft.

Maryland

BALTIMORE—The Zirconium Co. of America, recently organized with a capital of \$1,000,000 to manufacture ferrozirconium and a refractory specialty known as zirconium oxide, has acquired an interest in the plant of the Rare Metals Reduction Co., Old Frederick Rd., Catonsville, and will use the property in connection with its proposed new plant in this section. George F. Dixon is president and Philip C. Spencer vice-president.

MOUNT SAVAGE—The Mount Savage Fire Brick Co. has awarded a contract to Golin Gerlach, Frostburg, Md., for the construction of additions to its plant to cost about \$85,000. The work will consist of a new kiln building, 100x200 ft., and two other buildings, 98x286 ft., and 36x325 ft., respectively, with power house, 50x90 ft.

BALTIMORE—The Crown Oil & Wax Co., Eighth and Pratt Sts., is said to be planning for extensions and improvements at its plant to cost about \$25,000.

BALTIMORE—The Cooknut Corp., Lexington and Paca Sts., W. R. Spruill, president, recently organized with a capital of \$500,000 to manufacture lard substitutes and kindred products, is planning for the early erection of the first unit of its proposed new plant, to have an initial capacity of about 55,000 lb. per day.

Michigan

ROCKFORD—Machinery will be installed at once at the new local plant of Henry Ford, Detroit, for the manufacture of plate glass under a new process. A large portion of the output will be used for Ford automobiles. The company has extensive silica deposits in this section, claimed to be particularly suitable for the desired character of glass.

Missouri

KANSAS CITY—The Barada, Gordon & Page Chemical Co., 2018 Guinotte St., has awarded a contract to the McCallum Construction Co. for the erection of a new plant, 40x60 ft., on Michigan Ave.

New Jersey

PERTH AMBOY—Fire April 6 destroyed a portion of the local plant of the General Bakelite Co., 350 Rector St., with loss estimated at about \$15,000.

New York

BUFFALO—The Standard Milling Co., 49 Wall St., New York, has plans under way for its proposed new flour mill at the foot of Louisiana St., Buffalo. The mill, it is said, will be the largest plant of its kind in the world. It will comprise two elevators of 3,500,000 and 2,500,000 bu. capacity, respectively. Four complete flour mill units will be constructed, each with an output of 6,000 bbl. per day; a rye mill of 300 bbl. daily output; wheat mill of 300 bbl. capacity; corn mill of 500 bbl.; and oatmeal of 600 bbl. The new plant with machinery is estimated to cost about \$7,500,000. The A. E. Baxter Engineering Co., Ellicott Sq., Buffalo, is engineer.

CORNING—The Illig Cut Glass Co., East Market St., will soon take bids for the erection of a 1-story addition at Denison Parkway and Pearl St., 45x45 ft. John Illig is head.

Ohio

BREMAN—The Breman Metal Stamping Co. has plans under way for the erection of a 1-story addition, 28x70 ft. W. E. Trinkey is head.

LANCASTER—The Interstate Glass Co., Bradford, Pa., is having plans prepared for extensions and improvements in its plant at Lancaster to cost about \$70,000. H. J. Walters is president and general manager.

CAMBRIDGE—The Flannagan Pottery Co. has awarded a contract to Gamble & Bryan, East Liverpool, O., for the erection of a new kiln building to cost about \$20,000. It will be used for decorative work.

Oregon

PORTLAND—The Portland Flouring Mills Co. has arranged for a bond issue of \$3,000,000, the proceeds to be used, in part, for proposed extensions and betterments in its different plants.

Pennsylvania

PITTSBURGH—Fire March 31 destroyed a portion of the building of the Pennsylvania Paper Stock Co., with loss estimated at close to \$100,000.

PITTSBURGH—The Air Reduction Co., 2555 Liberty St. and 120 B'way, New York, manufacturer of commercial oxygen, etc., is having revised plans prepared for the erection of its proposed new plant on Ridge Ave. to cost about \$250,000 with equipment.

PORT KENNEDY—The Valley Forge Magnesia Co. has awarded a contract to the William Steele & Sons Co., 1600 Arch St., Philadelphia, for the erection of its proposed new local plant, comprising a 2-story building, 40x100 ft., and 1-story structure 40x48 ft.

Tennessee

KNOXVILLE—H. L. Dullin, affiliated with Anderson, Dullin & Varnell, is organizing a new company for the establishment of a new plant for the production of acid phosphate and kindred specialties.

KNOXVILLE—The Knoxville Fertilizer Co., recently organized with a capital of \$500,000, has plans under way for the erection of a new local plant. James W. Dean and S. B. Carter head the company.

MARTIN—The E. E. Gooch Mfg. Co., recently organized, is planning for the erection of a new plant for the manufacture of Skipper and other compounds. The installation will consist of grinding and mixing machinery, packing equipment, etc. The different machines will be electrically operated. E. E. Gooch is president and general manager.

Texas

HOUSTON—The Standard Rubber Co., Mason Bldg., has acquired the plant of the Universal Tire Co. for the establishment of a new rubber goods manufacturing plant. It is said that the plant will be remodeled and improved. E. H. Fleming is president and John T. Powers, Jr., secretary.

SAN ANTONIO—The Samuels Art Glass Co. has acquired a local site with about 100 ft. frontage for the construction of a new 3-story plant. L. M. Samuels is head.

SAN ANTONIO—Charles R. Tips, San Antonio, is organizing a new company for the construction of a glass-manufacturing plant at Three Rivers, near San Antonio. The initial works will be of 3-tank type, and will be devoted exclusively to bottle production. The company has its own silica properties in this district. The new plant is estimated to cost about \$30,000.

Washington

SPOKANE—The Northwest Iron & Steel Co., Rookery Bldg., is planning for the erection of a new iron furnace in the Boundary district of Stevens County. The plant will have an initial output of 25 tons per day, and at a later date, it is said, will be enlarged and improved.

West Virginia

ELLENBORO—The Insulite Co., recently organized to manufacture molded composition products, etc., has awarded a contract to J. M. Worstell, Ellenboro, for the construction of its proposed new plant, 80x160 ft. A number of machine tools in addition to regular operating equipment will be installed, including lathes, drills, grinders, etc. A power house also will be constructed. Edward J. White is president and manager.

HUNTINGTON—The International Nickel Co., 43 Exchange Pl., New York, has awarded a contract to the McClintic-Marshall Co., Oliver Bldg., Pittsburgh, Pa., for the erection of its proposed new plant at Huntington for the manufacture of rolled nickel products. The plant will consist of a group of 1-story buildings, approximating 200x400 ft. in size, including rolling mill and other departments. It is estimated to cost in excess of \$2,000,000 with machinery. Frank I. Ellis, Farmers' Bank Bldg., Pittsburgh, is consulting engineer for the project.

SUTTON—The Sutton Building Corp., recently organized, is planning for the erection of a local plant for the manufacture of brick, tile and other burned clay products. Benton B. Boggs is president.

New Companies

THE SUPERIOR SPARK PLUG Co., Detroit, Mich., has been incorporated with a capital of \$25,000 to manufacture spark plugs and other ignition equipment. The incorporators are I. J. Pettiford, Z. W. Laskalin and George Hadrich, 4001 Bewick Ave.

THE INTERNATIONAL ENGINEERING & CHEMICAL CORP., Boston, Mass., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are C. Binnig, Benjamin J. Phipps and Samuel Arafe, 41 Draper St., Dorchester, Mass.

THE DRAGON DRUG & CHEMICAL Co., Brooklyn, N. Y., has been incorporated with a capital of \$300,000 to manufacture chemical products. The incorporators are G. B. Rose, S. Marchisio and J. Furcht, 26 Court St.

THE J. J. MURPHY PAPER Co., New York, N. Y., has been incorporated with a capital of \$125,000 to manufacture paper products. The incorporators are M. Syrkin, A. Aaronson and J. J. Murphy, Orange, N. J.

THE DE LUXE INK & DYE Co., 716 Ashland Blk., Chicago, Ill., has been incorporated with a capital of \$40,000 to manufacture ink, dyes and kindred products. The incorporators are Sampson Andalman, M. King Schragar and Samuel J. Green.

THE MOSCO REFINING Co., Newark, N. J., has been incorporated with a capital of \$25,000 to manufacture oil products. The incorporators are John J. McLean, Charles S. Halleron and William D. Duguid, 87 Irving St.

THE BAY STATE FIBRE Co., Portland, Me., has been incorporated with a capital of \$10,000 to manufacture fiber products. E. M. Pine is president; Edmund P. Mahoney, treasurer; and Jacob H. Berman, secretary.

THE EUCCO CHEMICAL Co., Tonawanda, N. Y., has been incorporated with a capital of \$25,000 to manufacture chemicals and byproducts. The incorporators are G. L. Corliss, C. L. Pack and W. W. Britt, Tonawanda.

THE SAGINAW CLAY PRODUCTS Co., Saginaw, Mich., has been incorporated with a capital of \$30,000 to manufacture burned clay specialties. The incorporators are F. J. Lohman, Henry W. F. and J. Fred Goetz, Saginaw.

THE LOS ANGELES-VENTURA OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are J. B. Harker, Charles I. Puffer and M. H. Serf, Los Angeles. The company is represented by C. E. Hobart, 500 Wilcox Bldg.

THE NORTH WEST ENVELOPE Co., Seattle, Wash., has been incorporated with a capital of \$50,000 to manufacture paper products. The incorporators are L. V. Carey and associates.

THE MERIT OIL Co., 355 East 47th St., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture oil products. The incorporators are Leo and Jacob Adler, and Charles A. Schram.

THE VELVO OIL Co., Utica, N. Y., has been incorporated with a capital of \$150,000 to manufacture refined oil products. The incorporators are F. A. Hoyt, J. A. Ritchie and F. M. Tobin, Utica.

THE COLUMBIA CHEMICAL CONSTRUCTIVE CORP., Philadelphia, Pa., has been incorporated under Delaware laws with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are Fred J. Bergmann, Fred W. Moesta and Edward Ramsey, Philadelphia.

THE INDUSTRIAL MOLDED MATERIALS Co., Woodbury, N. J., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture molded and compounded specialties. The incorporators are Harry M. Dent, Robert G. Griswold and Paul Knapp, Woodbury.

THE LEO DREYFUS Co., New York, N. Y., has been incorporated with a capital of \$250,000 to manufacture chemicals and chemical byproducts. The incorporators are L. Dreyfus, S. D. Kessler and J. Herron, Jr. R. Seelav, 51 Chambers St., New York, represents the company.

THE BURGESS PAPER Co., 37 West Van Buren St., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture paper specialties. The incorporators are Roy H. and Frank A. Burgess, and Edwin I. Hoke.

THE CHEMICAL GAS DEVELOPMENT Co., Vancouver, Wash., has been incorporated with a capital of \$300,000 to manufacture chemical products. The incorporators are

A. S. Battson, E. D. Payne and F. L. Naul, Vancouver.

THE SUPERSOAP PRODUCTS Co., New York, N. Y., has been incorporated with a capital of \$10,000 to manufacture soap and kindred products. The incorporators are J. Sokoloff, M. M. Sokoloff and J. Stollmaker, 162 East 161st St., Bronx.

THE WILLARD BRICK Co., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture brick and other burned clay products. The incorporators are A. F. Hanrahan, W. F. Davis and E. A. Vosseler. The company is represented by E. W. Webb, 149 B'way.

THE HUNTINGTON OWNERS' OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are J. E. Yerby, B. S. Carr and M. P. Hansen. B. S. Hunter, Citizens' National Bank Bldg., represents the company.

THE APEX OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000 to manufacture petroleum products. The incorporators are Arthur G. Gage, Fred H. Hammer and M. L. Jenks. The company is represented by Adams, Adams & Binford, 716 Van Nuys Bldg.

THE FORT WORTH ENVELOPE Co., Fort Worth, Tex., has been incorporated with a capital of \$10,000 to manufacture paper products. The incorporators are J. A. Stafford, E. C. and W. C. Lowden.

THE CHEMICAL PRODUCTS Co. OF NEW JERSEY, INC., Newark, N. J., has been incorporated with a capital of \$1,000,000 to manufacture chemicals and chemical byproducts. The incorporators are George A. Soden and Alfred Gable, Newark; and S. Ellsworth White, Glen Ridge, N. J.

THE MONUMENTAL OIL CORP., Baltimore, Md., has been incorporated with a capital of \$25,000 to manufacture lubricating oils, greases, etc. The incorporators are Howard M. Roberts, Stuart S. Scott and Charles D. Smith, 110 South Charles St.

THE ALLOY ORE & MINERAL Co., 128 Market St., Newark, N. J., has filed notice of organization to manufacture alloys, ore specialties, etc. Irving N. Schafman, 212 Elizabeth Ave., heads the company. The same interests have formed the Asbestos & Magnesia Co., Superb Bldg., to manufacture asbestos products, and the Atlantic Gulf & Pacific Oil Co., to manufacture oil specialties.

THE R. A. HUDSON Co., Auburn, N. Y., has been incorporated with a capital of \$175,000 to manufacture chemical and chemical byproducts, drugs, etc. The incorporators are N. D. Stone, W. T. and R. A. Hudson, Auburn.

THE MID-WEST DRUG Co., Akron, O., has been incorporated under Delaware laws with a capital of \$100,000 to manufacture chemicals, drugs and affiliated products. The incorporators are Edgar M. Williams, Akron; Albert B. Smith, Chicago; and L. J. Rothenbecker, Cleveland, O.

THE ART PARAGON PAPER BOX Co., 531 South Peoria St., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture paper boxes and kindred specialties. The incorporators are Abraham, Louis S. and Samuel S. Berman.

R. A. FAWCETT, INC., Boston, Mass., has been incorporated with a capital of \$50,000 to operate a leather tanning plant for hides, skins, and for the production of byproducts. The incorporators are Benjamin Hemmerlin, 161 Summer St.; A. T. Parsons and L. A. Smith, Boston.

THE AUTO CITY OIL Co., Detroit, Mich., has been incorporated with a capital of \$10,000 to manufacture lubricating oils. The incorporators are Marble I. Tweedle and August L. Miller, 5441 Iroquois Ave., Detroit; and W. H. Stavk, Cleveland, O.

THE INTERSTATE TANNING Co., Newark, N. J., has been incorporated with a capital of 2,500 shares of stock, no par value, to manufacture leather products. The incorporators are W. R. Crosson, Willard S. Muchmore and A. P. Bachman. The company is represented by James B. Reilly, 31 Clinton St.

THE TRENTON FOLDING BOX Co., Trenton, N. J., has been incorporated with a capital of \$125,000 to manufacture paper boxes and kindred products. The incorporators are A. E. Serridge, Edwin W. Arnold and George F. Vanaken, Trenton.

THE ARUNDEL OIL CORP., 7 East Redwood St., Baltimore, Md., has been incorporated with a capital of \$400,000 to manufacture oil products. The incorporators are William A. Smith, Bruner R. Anderson and John A. Vogt.

THE KEYSTONE FIREBRICK Co., Philadelphia, Pa., has been incorporated with a

capital of \$150,000 to manufacture firebrick and other refractory products. The incorporators are A. M. Davis, James Warnock, Philadelphia; and Walter L. Hachnlen, Cynwyd, Pa.

THE CHARLES E. LESTER Co., New York, N. Y., has been incorporated with a capital of \$20,000 to manufacture chemical products. The incorporators are E. S. Bachrach, D. Rieser and W. Strauss. H. Hofheimer, 35 Nassau St., represents the company.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN PAPER & PULP ASSOCIATION is holding its annual meeting at the Waldorf-Astoria and Hotel Astor, New York City, April 11 to 15.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN WELDING SOCIETY, METROPOLITAN SECTION, will hold its regular meeting April 19 at the Engineering Societies Building, New York City.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

ASSOCIATION OF SCIENTIFIC APPARATUS MAKERS OF THE U. S. A. will hold its meeting at the Hotel Raleigh, Washington, D. C., April 14 to 16.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon, April 26, at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

TECHNICAL ASSOCIATION OF THE PULP & PAPER INDUSTRY is holding its annual meeting at the Waldorf-Astoria and Hotel Astor, N. Y., April 11 to 14.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Wanted—

A Taragometer

ALL YOU have to do is to invent it and develop it and produce and market it successfully, and—there you are! The instrument is sorely needed. Those of our readers who have enjoyed the benefits of a classical education sufficiently to remember their Greek, and any who may be engaged in small-scale roasting and vending of peanuts, and are, like most of their colleagues, themselves Greeks, will readily understand the nature and purpose of the apparatus. It measures noise.

The late JOSEPH PULITZER, editor and owner of the *New York World*, could not stand noise at all. He was a great editor and a man who, although blind, was gifted with rare mental vision; but noise drove him wild. Being very rich, he had sound-proof rooms constructed in his house for his comfort, and when he traveled he engaged rooms above and below and all around the apartment that he occupied at a hotel. The rest of us have to stand it, but it is not good for all of us. Psychologists are beginning to make records of the effects of raucous, persistent and nerve-racking noises, and the results are worse than expected. They upset the delicate balance of the mind, which is a sensitive apparatus, even among those who exceed in dullness. The riveter may not mind it, because to drive rivets is his chosen calling, but he doesn't have to think much. It is constructive thought that is disturbed by noise; constructive thought and health—mental health. It would be interesting to learn whether boiler-makers and others who live in such rattles are not more addicted to beating their wives than those who dwell in peace. The half-hushed rumble of a city or the distant roar of a waterfall is often soothing, but there are noises, more especially factory noises, that never soothe. Many of them are unnecessary and some of them cost money.

Every bit of unnecessary noise is wasted energy, and when we say unnecessary we mean a strict construction of the adjective. Those who are heavy of wit need emphasis, but if we put it on where it is not needed we not only hurt, we injure. Those of us who engage in thoughtful occupations do not like to be yelled at, and those of us who work with our hands can do better without it.

We know of a laboratory that moved from a noisy street to a quiet place, and as soon as the chemists were freed from the racket and rumble and dust their work improved and their ideas were better. This also holds true of an artisan who needs to use his head at his work. He can't do as well if his ears are constantly recording alarms as he can if given a decent quiet place for his task. Nearly everyone who is sensitive has a little of the PULITZER in him in so far as he is disturbed by noise, while those who are not sensitive cannot make the fine distinctions that we want our best men to make. Noise spoils good work. It is a good thing to bear in mind

that we ourselves shall not only do better but also get better work done, if we make less noise. There is too much entropy in noise for it to be wholesome. One of the wisest men of science we know declares that entropy is original sin. We favor the idea.

So let's have the taragometer. It will record in degrees the raucousness, the unpleasantness, the nerve-stretching quality of noises wherever it is installed, and do it quantitatively. It will prevent accidents. Noise distracts, and the distracted brain cannot work.

Our idea of the Garden of Eden is that ADAM ate the forbidden fruit all right just as it is recorded, but that the apple was green and it griped him. Thereupon he lifted up his voice in pain, and a wise PROVIDENCE on hearing the noise determined that with such a racket the Garden ceased to be Paradise, and the result has been duly taught to all of us. Unnecessary noise is entropy, it is original sin, it causes accidents, inhibits good work, and provokes insanity. We need the taragometer.

Strangling Business by Too Much Organization

LATELY we had a little talk with a Chinese merchant about his business. Production, he said, was a simple problem, but selling in the United States was the very devil. "You can't drive it into the heads of buyers," said he, "that China is farther away than France or Italy." "Send your samples and name your prices, and then I'll tell you whether we will buy or not," they say. This means, it is explained, that deliveries come along nine months later, which is too long a time. Letters take more than a month in transit, and so do packages. "Give me," says the Chinese merchant, "samples of what you want, and the highest price at which the goods made in China will interest you. Then I will cable you my figure, which may be a quarter or even half off your price, if you name me present costs; and I will guarantee quality and insure delivery." "We don't do business that way," say the buyers. "We refuse to give up our patterns, and we demand deliveries three weeks after the cable order." Then the Chinese merchant goes to the head of the firm, shows what he can do, and how he does it, and the merchant understands. He appreciates the big killing to be made with Chinese goods, and sends for the buyer, who listens again to the story already told him, but the buyer repeats the statement that "that isn't the way we do business." He or she doesn't know any other way, because no matter how often it is explained "it isn't done."

The merchant is in the hands of his buyers, of whom so many are wooden-headed that he does not know how to get better ones, and time and again orders that are desired are lost for the very reason we have given.

The old gentleman who understands and wants to buy

is himself to blame. He has overorganized his establishment. He has so firmly fixed "the way we do business" that it has become gospel among his employees. It is even more stolidly established than Chinese tradition. He has killed initiative among his buyers so that a person who thinks for himself does not want the job, and the wooden-heads increase and multiply under him.

If we want good work done we must make it interesting; otherwise we can't get competent and high-class men and women to stay on the job and do good work. If we overorganize our business we are bound, in the long run, to surround ourselves with dullards.

Some Steel

Price Comparisons

SUBSTANTIALLY identical prices, as between the United States Steel Corporation and the independent steel producers, have developed again, and comparison of prices at various times is befitting. The course of steel prices may be reviewed briefly. The general substitution of mild or soft steel for wrought iron was completed before the end of the industrial depression of 1893-98, and by a combination of rich Mesabi ores, low wages and economies generally very low prices ruled in 1897 and 1898. Afterward there were various ups and downs and at the end of 1914 the lowest prices since 1898 were reached. Leaner ores were then used than in 1898 and wages were about 50 per cent higher, but manufacturing processes were much better.

During the war steel prices advanced and after the entrance of the United States the advances were spectacular. Then came Government price control. Dec. 13, 1918, slight reductions were made by the mills, as a step in deflation, and through the instrumentality of Secretary REDFIELD'S Industrial Board further reductions became effective March 21, 1919. From then until last week the United States Steel Corporation adhered to the Industrial Board prices. The independents at first cut those prices, until some time in June, 1919, and late in the year they advanced over those prices, while in 1920 there was a wildly advancing market on the part of the independents, with continued expectation on their part that the Steel Corporation would advance its prices. Such expectations were disappointed, and by the end of 1920 the independents were back to the Industrial Board or Steel Corporation prices. During January of this year there was a uniform market, while in February the independents began cutting. Early in April the independent market firmed up somewhat and then, effective April 13, the Steel Corporation made certain reductions in its prices, whereby the independents and the Steel Corporation are again at the same level.

Using a weighted average of the important steel products according to their tonnage importance, including bars, shapes, plates, pipe, wire, sheets and tin plate, a fairly complete summary of steel price movements can be made in small compass, as given below:

Ten-year average, 1904-1913.....	\$ 36.00
Five-year average, 1909-1913.....	34.00
Year 1913	34.50
Dec. 31, 1914.....	28.50
High, July 1, 1917.....	114.00
Government control	76.00
Dec. 13, 1918.....	72.00
March 21, 1919.....	65.00
Independent high, 1920.....	93.00
Dec. 31, 1920.....	65.00
Independent low, March 1, 1921.....	57.50
Present general market.....	60.00

In price comparisons in general of late, various bases for a pre-war level have been taken, and in the foregoing presentation several are therefore given for steel. The figures represent prices in dollars per net ton as a weighted average of the finished products just mentioned.

Pre-war averages are much the same, whatever period of years be taken as a basis, but pre-war high and low points are a different thing. We are not looking now for pre-war prices, for neither wages nor freight rates will get back to pre-war levels, but there is room for argument as to whether we should look for prices in relation to pre-war averages or prices in relation to pre-war low points.

Taking \$35 as a mean of pre-war averages, the present finished steel market is 71 per cent above that basis. On the other hand, it is 35 per cent below the high prices of independents in 1920, not the highest prices charged on small lots for prompt shipment, but the prices obtained on moderate sized lots for ordinary deliveries. It is 21 per cent below "Government prices" and 47 per cent under the very fancy prices ruling just before the Government undertook to take control as a necessary war measure.

Can we compare the 71 per cent excess in steel prices over the pre-war average with the relations that other commodities show to their pre-war averages? Some undertake to do so, but the showing depends simply upon what commodities are taken. Tin, copper, antimony, aluminum, lead and zinc are all below their pre-war averages. According to a statement prepared by the Bankers Economic Service, rubber, compared with its average Feb. 1 in each of the five pre-war years, is at 18 per cent, or less than one-fifth price, hides are at 62 per cent and coffee (wholesale) is at 63 per cent. Brick and lumber, on the other hand, are at more than double price, 264 per cent and 222 per cent respectively, while cement is set at 317 per cent.

Steel, apparently, would search in vain outside the industry for a standard. The industry will have to develop its price level from within.

Necessary Operating Conditions To Avoid Smoke Damage

JUDGE JOHNSON'S final decree in the Salt Lake Valley smoke suit, now at hand, impresses one as being quite unusual in that it apparently is able to point the way whereby smelters can operate with no interference to their development and future improvement and yet establish no nuisance to the neighboring residents.

Time was when any rancher, on finding his crops marked in any way or his stock drooping, or for that matter, if his own head ached, would sniff the air for smoke and join with his neighbors to sue for damages or to exjoin operations at any smelter within twenty-five miles. All damage was smoke damage. Many fanciful claims were advanced by the plaintiffs, and as we know now, almost as fanciful defenses set up. A vast amount of human energy and good feeling was spoiled in these squabbles; the operating companies upon which the bulk of the expense rested have spent sums of money easily aggregating millions in fighting unwarranted claims, in settling just claims, and in purchasing easements or damaged property. A half dozen or more plants stopped operations rather than face what seemed to be continuous guerilla warfare; their losses ran into millions more.

In those days arsenic, lead and sulphuric acid were thought to be the chief culprits; consequently courts decreed that extensive dust chambers, bag houses and flue systems must be installed to catch all but traces of these substances. Furthermore, the total tonnage of sulphur eliminated daily was usually specified, thus strictly limiting the amount of ore smelted in one place. Such stipulations, together with others limiting the SO_2 concentration in main stack gases, gave evidence that courts recognized the potential danger of that gas long before operating companies would admit the fact. Fortunately for the smelters, big dust chambers and long flues required draft, and draft was easiest had by high chimneys. High chimneys allowed the smoke to dilute itself in the atmosphere before again reaching the ground, and the real danger was thus inadvertently minimized.

Investigations of high scientific merit, continued during the past ten years and summarized from time to time in these columns, have made it plain that SO_2 would produce characteristic markings on the foliage of growing plants. This was something of a poser to those managers who had deluded themselves with thinking that if their smelter stacks showed no smoke—no visible fume, unconsumed carbon, or condensing vapors—then no damage would result. Or at least no damage would be ascribed by residents to smelter smoke. A further shock was due them when it was finally established that 1 part SO_2 per million for three hours would under optimum conditions produce foliar markings, and as little as 1.3 parts per million would do the same in one hour. In view of the fact that prolonged puffs of smoke are likely to sweep down at any time, it seemed that it would not be safe to operate a smelter so that the SO_2 content in the air of the so-called smoke zone would average more than 0.3 part per million—a dilution so high that operating officials freely declared it to be impossible of attainment. They almost fell into the error of denying the possibility of SO_2 damage, and the attempt to purchase peace by a discreet claim agent.

The more far-seeing and stout hearted, however, viewed the problem of dilution as one which could be solved. Theoretically, of course, it could be done by enormously high stacks or infinitely hot gas. The former was economically impossible, the latter would defeat the aims of metallurgy. A compromise, joining the correct chimney with a proper temperature above atmospheric, was evidently an engineering problem strictly, capable of definite solution when the necessary data had been collected.

The latest decree is therefore unique in several ways. It was postponed until the engineering solution had been found, put into operation, and finally investigated and found satisfactory by an independent commissioner. It may therefore be accepted, not only by courts as a precedent, but by smelter officials as a rule by which they can avoid damage to surrounding vegetation.

Given a modern smelter, with correct provision against leakage of smoke in the buildings or from the flue system, the principal precaution is that the dust-free gases be discharged from the main stack at a correct temperature above the atmosphere. In this decree no stipulation is made as to the amount of ore which may be smelted, the average sulphur on the charge, or the tons of sulphur eliminated. No reservation is taken as to the concentration of SO_2 in the

stack gases, nor the method of clearing them of solids; in fact, it may be remarked that probably for the first time the Cottrell system has been formally adjudged to be a satisfactory medium for collecting dust, fume and sulphuric acid, equal to the bag house.

In other words, while the SO_2 concentration in the stack gases, the chimney height, the topography, wind prevalence and general weather conditions all have their influence, it may now be taken as quite probable that foliar markings during the growing season may be entirely eliminated, no nuisance established in the eyes of the court, if the smelter management pay proper attention to discharging the gas during the day time at a correct temperature. What that correct temperature difference is may be established with relative certainty and at less than the cost of one damaged crop by merely studying the relation between average field concentrations, stack concentrations and stack temperatures. For the present Murray plant the figure happens to be 75 deg. C.

A General and Particular Confession of Pharmaceutical Fault

EVERY time we mention rats we get into trouble. Years ago we ventured to propose the tanning and use of rat skins as a means of getting rid of the pests, and the correspondence which followed from persons ambitious to profit by our suggestion included letters from a young man eager to enter the rat business, the secretary of a Woman's Vocational Association willing to sell tanned hides but unwilling to catch or touch rats, and a hardy son of toil who threatened to send rat skins to the office. It nearly upset us. We had a "scientific management" man in the establishment then who figured up inches of space and tabulated everything. It messed up his tables. It took us months to get over it, and the only compensation was Dr. ROEBER'S chuckle of delight over the episode.

Lately we mentioned, in an editorial on the chemistry of olfactics, a note from the London *Daily Mail* that rhodium was a wonderful lure for rats, and, being botanically ignorant, we tried to find a little amusement in quoting an eminent electrochemist to the effect that if the rodents liked rhodium they would probably take to platinum, and that they might be used to find it, for LORD knows it is scarce enough!

Now we confess ignorance for ourselves and for our entire staff in this respect. Probably we should have a department of pharmaceutical chemistry, but we haven't. Apparently, however, we have friends who are more familiar with botany and pharmacy than we are, and about a dozen of them have written to chide us for our ignorance. These letters make us humble and we confess it openly. They are printed elsewhere in this issue and will afford the reader a smile at our expense.

We do not know the name or address of the printer or the writer of the article in the London *Daily Mail*, but if Mr. ANDREWS can find them for us we promise the printer a good free-smoking hand-made Havana filler cigar, and a Flor de Convolvulus Scoparius to the author. There is a crumb of comfort for us in Mr. CRAIG'S note that rodent bait is not really and truly oil of rhodium after all, but we make no claim for a bill of wisdom in the assertion. The real mistake was ours, rhodium is a plant or a shrub or a tree as well as a metal and we did not know it.

Readers' Views and Comments

Rhodium for Rodents

To the Editor of Chemical & Metallurgical Engineering

SIR:—Anent your editorial on olfactics: Rhodium is rosewood. See "Condensed Chemical Dictionary," page 404. The name was in use before the metal rhodium was known.

D. D. BEROLZHEIMER.

New York, N. Y.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 502, of the March 23, 1921, number of CHEM & MET., under the heading, "The Chemistry of Olfactics," at the end of the third paragraph you close with the following: "We wonder what the London writer wrote that the printer mistook for rhodium!"

It is perhaps not to be wondered at that an ex-president of the Electrochemical Society thought that a metal was meant and that perhaps a rat might be trained to track down any missing articles of rhodium or platinum, but I am sure that what the London writer meant and wrote was rhodium, which is the wood of *Convolvulus scoparius*, or rosewood. From this a volatile oil is obtained which is used as a bait for some animals. You will find this on page 404 of the "Condensed Chemical Dictionary." I think that you owe the unknown London writer a cigar.

A. B. ANDREWS.

Lewiston, Me.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—You are puzzled to know what is "oil of rhodium," on which rats (rodents) are so keen. Oil of rhodium or rodium was a nostrum, very familiar to youngsters before the civil war. It was used to bait fish as well as rats; all that was necessary was to buy a small—very small—phial of the widely advertised stuff at a drug store for an exorbitant price and use a drop of it on the fish-hook. I do not remember anything more about it except that my experience with it, as a small boy, led me to believe that it did not attract the fish.

W. GEORGE WARING.

Webb City, Mo.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—Some cynical person has said that the mishaps of our friends are never wholly unpleasant to us, and I must confess that I could not repress a chuckle after reading the interesting editorial entitled, "The Chemistry of Olfactics," which appeared on page 502 of your issue of March 23.

Did no guardian angel whisper to you to look in the dictionary to see whether there were not some kind of rhodium other than that with which you are familiar before you let go those flippant remarks about the use of rats in prospecting?

The story of the geologist reminds me of an equally famous one about the sea captain who could always tell the location of his ship by the taste of the earth that came up adhering to the bottom of the lead. One night when he was nearly asleep in his bunk the first mate thought to play a trick on him and so stuck the end of the lead into a flower pot that they had on board and then presented it to the captain to taste. To his great surprise, the captain leaped from his bunk and shouted

aloud: "Nantucket is sunk and we are right over Ma Jones' garden!" The story about the blind deaf-mute does not stagger my credulity, because when I lived in China I was able to apply a somewhat similar system to my Chinese servants, depending on whether or not they preferred garlic or peanut oil in their food.

T. T. READ.

Washington, D. C.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—Referring to your editorial "The Chemistry of Olfactics" will say that rhodium oil is not by any means an uncommon substance. This is another name for oil of rosewood from *Convolvulus scoparius* and *Convolvulus floridus*, coming from the Canary Islands.

Syracuse, N. Y.

WILLIAM BOOTH.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—The editorial section of this journal is usually so accurate and its policy in general so correct that a little malicious satisfaction at the slip made in the issue of the 23d inst. in the discussion of the odor of rhodium as being attractive to certain animals may be pardoned.

The rhodium referred to by the British correspondent is not the metal of the platinum group, but an oil distilled from a *Convolvulus* growing in the Canary Islands, and is used as an adulterant of oil of roses. It has also been used very extensively by trappers and hunters to attract animals to their traps, and was so used for many long years before the discovery of the metal rhodium.

It is a pity to thus "muss up" the elegant scheme of the ex-president of the Electrochemical Society relating to a rat detective corps for platinum thefts.

Washington, D. C.

WELLINGTON B. JOHNSON.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—Long before I had ever heard of rhodium, the element, in my days as an apprentice-apothecary, I was well acquainted with the rhodium of the catcher of rats, mice, muskrats and such vermin and rodents generally. The title in full is oil of rhodium. In some early textbooks it is Latinized as *Oleum ligni rhodii*. I believe that it is derived from *Genista canariensis* or some allied plant. Its use is most largely in the adulteration of oil of rose. In truth, the rodent-bait is not real oil of rhodium but copaiba scented with oil of rose or with oil of rhodium.

Ain't it true as how to the chemist all is chemical; to the botanist all is botany—to the editor (I admit the epithet) all is—what-in-ell is it anyhow? Yours for a broader life (Volstead volens).

HUGH CRAIG.

Oil, Paint and Drug Reporter,
New York City.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—I presume that by this time the interesting hypothesis that the olfactory sense of rats might be utilized as a reagent for the platinum group of metals has been given up, and that you have ascertained that

what the London writer wrote was, in fact, rhodium; or more explicitly, oil of rhodium, or rosewood (*Convolvulus* species); habitat, Canary Islands and elsewhere; odor, resembling roses and sandalwood, etc.

Not a very bad error for a metallurgical chemist; certainly more excusable than the reply of the wise lexicographer of a well known New York weekly who gave the meaning of the word "bitulithic" as "a chemical term, meaning two equivalents of the element thulium"!

F. D. DODGE.

Brooklyn, N. Y.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—In a recent editorial of your journal on the phenomena of odors you have apparently confused the metal rhodium with the herb by that name. See for example Lippincott's "Medical Dictionary"; under "Rhodium" there appears the definition as follows: "The root wood of *Convolvulus scoparius*, the oil of which has the odor of rosewood."

CARLETON ELLIS.

Montclair, N. J.

* * *

To the Editor of Chemical & Metallurgical Engineering

SIR:—I would like to correct an error in the editorial on "The Chemistry of Olfactics," which appeared in your issue of March 23, 1921. The writer of the editorial evidently takes "rhodium" to mean the element rhodium when he wonders why the rats are so keen on it. He even wonders what the London writer wrote that the printer mistook for rhodium.

Being conversant with the noble art of pharmacy, may I not point out that the joke is entirely on the writer of your editorial and in justice to his colleague of the London *Daily Mail* the mistake should be corrected.

Rhodium is the root of *Convolvulus scoparius*, growing in the Canary Islands. The oil obtained from this source is the article which was used as a lure for rats before the advent of the Pied Piper and Rough on Rats.

Columbia University,
New York City.

WILLIAM J. HUSA.

Dust Explosions

To the Editor of Chemical and Metallurgical Engineering

SIR:—We read with a great deal of interest the article on "Dust Explosions," by D. J. Price, in the March 16 issue of CHEMICAL AND METALLURGICAL ENGINEERING. On page 474, under the heading of dust removal, we note the following interesting paragraph:

In installations of this nature, a flammable mixture is usually formed when the dust passes through the exhaust fan. Explosions may be caused by the ignition of the dust by sparks from foreign material striking the fan blade or from the fan blade becoming loose. This situation has suggested the possibility of changing the location of the fan from its present position—namely, between the source of dust production and collection—to a position beyond the collector. In other words, can the dust be drawn into rather than blown into the collector?

We wish to draw the attention of the author of this article, and of engineers in general, to the fact that we have foreseen this danger and have eliminated all such fire and explosion hazards by placing the fan between the adjustable air separator and the centrifugal collector in our systems of dust collection. In all of our installations we have succeeded in removing the dust from the air, either partly or completely, before it is passed through the exhaust fan. The practical result is that in none of our installations has there been any fire or explosions.

CLARK DUST COLLECTING CO.

Cost of Nitrogen Fixation in Norway

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of March 23 you published an article by T. C. Hagemann on "Cost of Fixed Nitrogen in Norway." Under the heading "Steps in the Process" Mr. Hagemann states that: "The air to be treated is let into a chamber, where it passes through an electrical arc, which by some artificial means is given an increased area in order to heat the air so intensely that a part of the nitrogen burns—that is, combines with the oxygen and forms NO."

I have been fortunate enough to have seen the large plants at Rjukan, Norway, and have also made myself acquainted with the theory upon which the Birkeland-Eyde furnace is designed. To my knowledge of the question at hand Mr. Hagemann makes an error in stating that the arc "is given an increased area in order to heat the air so intensely," etc. Also Mr. Hagemann should have mentioned of what nature the artificial means were that gave the increased area to the arc. To me these two things appear to be of the utmost importance because they are the main features in making the Birkeland-Eyde process commercially successful; hence they should be correctly stated.

In the chamber water-cooled copper electrodes are employed, the arc being "started" by bringing one of the electrodes close to the other by means of a screw device. As soon as the spark "jumps" the gap the electrode is screwed away to increase the length of the arc. It is clearly seen that the efficiency would be very low if the air which is blown through the furnace could come in contact with only the comparatively narrow arc, hence Prof. Birkeland and Mr. Eyde, utilizing the well-known fact that a magnet will deflect the arc, placed a powerful magnet on one side of the arc and a similar magnet diametrically opposite. With one magnet functioning, the arc will be "pulled out" to a semi-disk. The two magnets are alternately charged and discharged with a very high frequency, thus making the two semi-disks appear to be a complete disk. This is of course not done in order to "so intensely heat the air" but in order to increase the area in which the air comes in contact with the intense heat of the arc.

To summarize, the artificial means are simply two electromagnets and the increased area is given in order to give a larger heating surface—not increased heat. Steps in a process of such merits as the Birkeland-Eyde process should not for a moment be allowed to become wrongly stated.

K. W. JENSEN.

Detroit, Mich.

The Border Lines of Colloid Chemistry

To the Editor of Chemical & Metallurgical Engineering

SIR:—On page 547 of CHEMICAL & METALLURGICAL ENGINEERING, March 30, 1921, there appears the following statement:

On the basis of our present chemical status, the colloid chemist may pass off the contribution by Dr. Loeb in this issue with the statement that his observations have been limited to dilute solutions and that Dr. Loeb has only confirmed a common belief that any properly dispersed substance in a proper degree of subdivision will obey the gas laws and the others derived from them.

May I be pardoned for pointing out that the solutions and the gels of proteins used in my experiments were no more dilute than those on which the colloid chemists have based their hypotheses?

JACQUES LOEB.

New York City,

The New President of "Tech"

DR. ERNEST FOX NICHOLS, physicist, the new president of the Massachusetts Institute of Technology, was born in Leavenworth, Kan., fifty-two years ago. He obtained his Bachelor's degree in science at the Kansas Agricultural College in 1888. Then he went to Cornell, where he was a graduate student in science from 1889 to 1892, and there he took his Master's degree. From 1892 to 1896 he was professor of physics at Colgate University, but in part time, from 1894 to 1896, he was at the University of Berlin with Prof. Rubens, where, in their joint work, they were pioneers in the modern study of infra-red rays. For a long time the infra-red rays measured by them were the longest that had been recorded. In 1897 he took the degree of Sc.D. at Cornell. During another interim, 1894-95, he studied at Cambridge University, England, and in 1898 he became professor of physics at Dartmouth. While there he undertook the problem of measuring the pressure of light, which had been open since the days of Maxwell. In this, working in conjunction with G. F. Hull, the outcome was successful, and they succeeded in proving and measuring with considerable accuracy the forward pressure which a beam of light exerts. Lebedew in Russia was engaged in similar studies and published his findings a month or so earlier, but his results were less exact, and rather of a qualitative nature as compared with those of Nichols and Hull, which were more definitely quantitative.

From 1903 to 1909 he was professor of experimental physics at Columbia University, New York. This was, in effect, a research professorship, and here he soon had a group of students making investigations in the infra-red spectrum, and working on the generation, reflection and diffraction of short electric waves. At the same time, on his own behalf, he engaged in the effort to check up experimentally some of the fundamental assumptions of the electromagnetic theory, and particularly that of moving charges of electricity.

In 1909 he was called to the presidency of Dartmouth, where he remained for seven years, and in 1916 he became professor of physics at Yale. During his professorship at Columbia he was research associate of the Carnegie Institution at Washington in 1907-09, and from 1917 to 1919 he was in the Bureau of Ordnance of the U. S. Army, so that the war gave him but little opportunity for work at New Haven. Last year he left Yale to take up research in pure science with greater facilities and a larger staff than any university can

offer, at the General Electric Co.'s laboratories at Nela Park, Cleveland. He has seven honorary doctorates and many medals and other distinctions.

More important than the details of his history is the manner of man that he is. He enjoyed the process of education in three countries: the United States, Germany, and England. His preference is for the English type of culture over that of Germany. His theory of an engineer is that he must first of all be an educated gentleman rather than a man with the recollection of many facts loaded upon a possibly insecure foundation of understanding. All thoughtful friends of Tech have recognized that the school might develop into an institution for highly specialized training on the one hand, or an institution of advanced and progressive scientific scholarship on the other. The selection of Prof. Nichols indicates that the trustees had in their choice the latter ideal in mind.

His change from research and teaching to administration and back again is in accord with his order of life. His interest in the general problem of education has always been acute, and at the same time he is an experimental physicist of the first rank. While president of Dartmouth he continued to teach. Before he accepted the post he told his friends that he would stay there for seven years, and at the end of seven years he did return to teaching and research. He thinks a long way ahead, and with precision.

He is reserved in manner, a man of dignity and yet excellent company, who does not carry his heart in his sleeve. He is kindly and helpful to earnest and competent students, an inspiration to those who are gifted with rare understanding and character, but has very little patience

with those who do not take their work earnestly or seriously.

His scientific curiosity is keen and persistent, but its tendency is rather toward fundamental problems than toward the filling in of unimportant gaps. While his habit of mind is large, it leans to the experimental rather than to the purely theoretical side. He has slight interest in the co-ordination of guesses, but immense interest in the co-ordination of facts. And he is richly gifted with common sense.

The late president, Dr. MacLaurin, had completed the first part of his work. His next task, at the time of his passing, was to be the internal development of Tech and the consolidation of its great resources of scholarship.

It is a big job. But we believe the trustees have exercised unusual wisdom in seeking and finding the right pilot.

DR. ERNEST FOX NICHOLS

CALIFORNIA ALKALI CO. PLANT

Salts-Refining Plants at Owens and Searles Lakes

Report of a Recent Survey of the Salts-Refining Plants Producing Natural Soda Ash, Borates and Potash in the Owens and Searles Lakes District of California

By L. W. CHAPMAN

OWENS LAKE, in Inyo Co., Cal., is the principal source of natural soda in the United States. Searles Lake, in San Bernardino Co., Cal., was the second largest producer of potash from a single domestic source in 1919 and probably retained that position in 1920; in addition, an appreciable quantity of borax is being recovered at the Searles Lake plants as a byproduct. At Owens Lake there are three operating companies and at Searles Lake there are four; with a single exception the plants have become producers during the last six years, and two of the plants will market the first of their product in 1921. These developments indicate an appreciation of the importance of the sources of raw material as well as an increase in the demand for the refined products. The amount of recoverable soda, potash and borax is not unlimited, but is sufficient to meet local demands for many years, and with economical methods of operation should play a prominent part in the industrial development not only of the West, but of the country as a whole. These notes describe briefly the geology of the district and the different processes now in use for obtaining commercial products.

GEOLOGICAL CONSIDERATIONS

Owens Lake, Searles Lake and Panamint Valley are to be considered together geologically, there being evidence that in Quaternary times they constituted a chain of lakes, the water, at that time probably quite fresh, flowing through the series in the order named. The drainage area of this lake system covers about 9,600 sq.mi. (24,900 sq.km.), and there are no indica-

tions that there ever was an outlet to the ocean. Owens Valley has an area of 2,800 sq.mi. (7,250 sq.km.), and is located between the Sierra Nevada Mountains on the west and the Inyo Range, a southern continuation of the White Mountains, on the east. The drainage area of Searles Basin is about 4,850 and of Panamint Valley about 1,950 sq.mi. (12,600 and 5,050 sq.km. respectively). Owens Lake is the only existing remnant of the lake system; the others are completely dry, except occasionally during the rainy season when a few inches of water may cover a portion of the crystal surface of Searles Lake for a few days.

Owens Lake changes considerably in area from year to year, depending upon the ratio of the evaporation to the inflow of water; the present level of the surface above sea level is 3,565.58 ft. (1,086.79 m.); it is approximately 13 mi. long by 8 mi. wide at the present time (21 by 13 km.). The rate of evaporation of Owens Lake brine is about 40 in. (1 m.) per year. During the last three years the water level has lowered quite rapidly; 40.5 in. (103 cm.) in 1918, 48 in. (122 cm.) in 1919 and 51 in. (155 cm.) in 1920, and this has had the effect of concentrating the salts in the brine. But little further evaporation is needed to make it possible to use the lake brine without solar concentration in the soda ash works.

The present area of the lake is about 42,000 acres (17,000 hectares) and the volume approximately 381,000 acre-feet (470×10^6 cu.m.). Dr. W. Hirschkind, of the California Alkali Co., estimates the quantity of salts in the brine to be, in million metric tons: Na_2CO_3 , 46.6; NaHCO_3 , 11.08; Na_2SO_4 , 19.4; NaCl , 51.5; KCl ,

OWENS LAKE, INYO COUNTY, CALIFORNIA

5.53; $\text{Na}_2\text{B}_4\text{O}_7$, 3.55. In the table are given analyses of the lake water, showing the effect of the level of the water in the lake upon the concentration of the salts. But a slight increase in concentration will cause crystallization of trona, $\text{Na}_2\text{CO}_3 \cdot \text{NaHCO}_3 \cdot 2\text{H}_2\text{O}$, during the summer months.

The relative position and elevation of Owens and Searles Lakes are shown in Fig. 1 and the Quaternary lakes are indicated. It seems probable that during the geological history there was more than one desiccation

superficially much like other playa deposits of the Great Basin region.² One very evident indication that the basin was occupied by a deep lake is the old shore line which is distinct at an elevation of about 635 ft. (193.5 m.) above the present surface. The basin is roughly circular, 15 to 20 mi. in diameter (24 to 32 km.). Near the center of the basin is an area about 12 sq.mi. (35 sq.km.) in extent, the surface of which is

²See G. J. Young, "Potash Salts and Other Salines in the Great Basin Region," Bull. 61, U. S. Dept. of Agriculture, for a geochemical description.

* Calculated from an analysis by Chatard, U. S. G. S. Bull. 60.

† Analysis by Natural Soda Products Co., Keeler, Cal. In October, 1920, the brine had a gravity of 1.23, with 28.4 per cent total salts.

and probably more than one period during which the waters flowed from Owens Valley through Indian Wells Valley and Salt Wells Valley into Searles Lake. Whether this had an appreciable effect on the relative composition of the brine remaining in Owens Lake and the crystalline deposit with its retained mother liquor at Searles Lake has not been determined, although Gale¹ is of the opinion "that these [Searles Lake] deposits are the normal product of the desiccation of a body of water of the same chemical character as the Owens Lake of the present time." It also seems probable that there was no considerable overflow from Searles Basin into Panamint Valley in what is to be considered recent geological history, and that therefore the greater portion of the deposited salts is the accumulation from the drainage system which includes both Searles and Owens Lakes, since this overflow. The water in Owens River comes principally from the Sierra Nevada Mountains, and at its present volume is adding more than 15,000 tons of sodium annually to Owens Lake. It is probable that part of the accumulation of salts in Searles Lake was derived from Owens Valley as well as from the much larger Searles Basin.

The dry lake basin that is known as Searles Lake is

Profile of the Former Owens Drainage System

FIG. 1. OWENS-SEARLES-PANAMINT LAKE SYSTEM

¹Bulletin 1894-L, U. S. G. S., by Hoyt S. Gale.

OWENS LAKE, INYO COUNTY, CALIFORNIA

composed of quite pure sodium chloride. Beneath this is the "crystal body," a coarsely crystalline deposit containing a large variety of minerals consisting chiefly of halite, thernardite, trona and borax. Gale³ reports sixteen, stating that the list is incomplete. Clark⁴ lists twenty-two; to these must be added glaserite,⁵ $3K_2SO_4$, Na_2SO_4 , and possibly some others. The crystalline deposit is from 65 to 75 ft. (19.8 to 22.8 m.) in depth and is saturated to within a few inches of the surface with a brine of the composition shown in Table II.

The brine is variously estimated to occupy from 25 to 40 per cent of the volume of the crystal body. It averages 4.2 per cent potassium chloride and 1.1 per cent anhydrous sodium tetraborate. Using the lower estimate for the amount of brine in the crystal body, the KCl content is over eight million tons, and the borax content over four million tons. This estimate does not include any salts that may be added to the brine through solution from the "crystal body," so that the amount of recoverable salts may be much greater.

The central salt deposit is surrounded by a margin of mud, clay and sand, incrustated with salts or impregnated with solution. The Argus Range on the west and north separates the Searles Lake Basin from Coso Valley, this being separated from Owens Valley by the Coso Range. The abrupt wall of the Slate Range divides the basin from Panamint Valley to the east.

OPERATIONS AT OWENS LAKE: INYO DEVELOPMENT CO.

Of the three plants at Owens Lake that of the Inyo Development Co. on the east shore of the lake was the first to be operated, soda ash having been produced at this plant since 1886. The plant is designed to produce a crude dense soda ash by melting trona, obtained by solar evaporation of the lake brine. The plant is now operated by the California Alkali Co. Brine from the lake is pumped into the series of solar evaporating ponds in the spring after the previous year's crop of trona has been harvested. The brine as it becomes concentrated in the first pond, due to evaporation, is run into the second pond of the series and the first pond is filled with water from the lake. This process is continued until a sufficient amount of sodium carbonate is contained in the ponds to give the required amount of trona in the sea-

son's crop. The concentrated solution finally is run into crystallizing ponds, and trona is precipitated. Toward the end of the season, usually in October, the nights become cool and if the solution remains in the ponds the cooling of the liquor will crystallize out a mixture of sodium carbonate and sodium sulphate as decahydrate. The concentration of the liquor and the temperature are watched and when there are indications that there is a possibility that the trona may be contaminated by the salt and sulphate the remaining liquor is run into the lake. As soon as the deposited salts are drained harvesting is begun. The trona forms a hard crust on the bottom of the ponds, which is broken up with picks and loaded into side-dump mine cars, which are hauled to the plant on a narrow-gage track by a gasoline locomotive. The trona is dumped into a bin, where it is washed with water, loaded into dump cars and hauled to a storage pile to dry.

The dried product is melted in the furnace shown in Fig. 2, crude oil being used for fuel. The molten carbonate runs in a thin stream into a blast of air which produces a globular product analyzing from 55 to 56 per cent Na_2O , less than 2.5 per cent Na_2SO_4 , and a small amount of NaCl. From 18,000 to 24,000 tons of trona is produced per year, which is in part converted into soda ash and in part marketed as such.

NATURAL SODA PRODUCTS CO.

On the east side of Owens Lake, about three miles south of the plant of the Inyo Development Co., is the plant of the Natural Soda Products Co. This was built

FIG. 2. FURNACE FOR MELTING TRONA, INYO DEVELOPMENT CO.

⁴F. W. Clark, "The Date of Geochemistry," Bull. 695, U. S. G. S.

⁵W. F. Foshag, *Am. J. Sci.*, vol. 49, May, 1920.

in 1915 and reconstructed after a fire in 1917. Melted soda ash has been the principal product, although crude trona and crude sodium bicarbonate have also been sold in small quantities. New equipment is being installed to produce a high-grade light soda ash.¹ After evaporating the lake brine in a system of solar ponds to the degree of concentration where trona will crystallize upon further evaporation, the concentrated liquor is pumped to carbonating towers. Carbon dioxide gas, obtained from kilns, is forced through the towers, precipitating sodium bicarbonate. The crystals are separated by filtration, air-dried in a storage pile (Fig. 3) and melted in an oil-fired furnace. The molten sodium carbonate is atomized by an air blast and the product is ground, screened and sacked for the market. Plant capacity is about 140 tons of this product per day. The new equipment will produce fifty tons of light ash, and a portion of the light ash can be converted into dense ash.

Limestone, in the form of a high-grade dolomitic marble, is obtained from a quarry about 9 mi. north of the plant. Coke is shipped from Utah. Rail transportation is provided by a narrow-gage line of the Southern Pacific which runs north to Mina, Nev., from the town of Keeler, on the east shore of the lake. Connection is made at Owenyo with the standard-gage line of the Southern Pacific running south to Mojave, Cal.

CALIFORNIA ALKALI CO.

At Catago, near the southwestern end of the lake on the standard-gage line previously mentioned, is the plant of the California Alkali Co. The method of operation is practically the same as at the Natural Soda Products Co., but no melted ash is produced and details of operation and equipment are somewhat different. Brine is pumped from the lake and concentrated by solar evaporation, and the concentrated liquor is filtered before carbonating. The bicarbonate is converted into

light ash in standard light ash furnaces, the product being of a very high grade. Dense ash furnaces are now being installed and a portion of the light ash now being produced will be made into dense ash. Total production will be about eighty tons a day.

As is evident from the brief description of the Owens Lake operations, the method of making soda ash is similar to the Solvay process, with the exception that no ammonia is used. Carbonating towers, furnaces and other equipment are of the standard design used in the alkali industry, except the furnaces for melting the crude trona at the Inyo Development Co.'s plant and for making the melted ash at the Natural Soda Products Co.'s plant, which are of special design.

Brine from Owens Lake is particularly suited for the manufacture of soda ash. The mother liquor from the carbonating tower contains both borax and potassium, the latter in the form of chloride. The liquor is not utilized at present, but it would seem possible to work out a method for profitably recovering these salts as byproducts of the soda ash operations. An experimental plant is being built by Wrinkle & Kuhnert for the production of borax and potash near the plant of the Natural Soda Products Co., and in the experimental runs will use the mother liquor from the carbonating towers after further solar concentration. The estimated capacity of the plant is ten tons each of potash and borax and twenty tons of sodium bicarbonate per day.

After the carbonates have been precipitated from the raw lake brine by solar evaporation, it is possible to crystallize from the residual liquor a crude sodium sulphate with which is mixed common salt. This material has a possible commercial value. It does not seem probable that salt can be produced at Owens Lake at a cost low enough to compete with that which is now being recovered from salt deposits in Inyo and San Bernardino counties, or with that obtained from sea water at plants near San Diego and San Francisco.

SEARLES LAKE OPERATIONS

Searles Lake was discovered by Dennis Searles and E. M. Skillings on Feb. 14, 1873, and 160 acres (64.75 hectares) of borax claims were located and patented by them.² Borax was first produced in 1874 and the deposit continued to be an important source of raw material until the discovery of the colemanite deposits in Death Valley and other localities in California. It would seem that C. E. Dolbear was the first to recognize the importance of Searles Lake as a source of potash, but the possibility of recovering potassium chloride was pointed out at about the same time by the U. S. Geological Survey. The first company to produce potash from the brine was the American Trona Corporation, which began active operations in 1915, first building a railroad 30 mi. in length from the line of the Southern Pacific to the lake. The company now has an investment in railroad, plant and equipment, housing facilities for the staff and workmen, water supply, etc., of over \$6,000,000.

AMERICAN TRONA CORPORATION

In outline the process of the American Trona Corporation is not complicated. Brine is obtained from wells drilled in the salt body, 500,000 gal. (1,900 cu.m.) being pumped per day to storage tanks at the plant.

Fresh brine, mother liquor and wash water are fed to triple effect 22-ft. (6.7-m.) Manistee evaporators and a hot solution concentrated with respect to KCl is obtained. This is cooled rapidly, first with raw brine and then by refrigeration, and a crop of KCl crystals produced. The crystals are separated from the mother liquor in centrifugals. Borax is recovered from the residual liquor and purified by recrystallization. Boiler equipment consists of twelve 500-hp. Babcock & Wilcox boilers, about 4,000 hp. being used. Evaporators con-

tain 40,000 sq.ft. (3,716 sq.m.) of heating surface per unit. Three 200-ton refrigerating machines are installed and about 400 tons per day is required for cooling solutions and other uses about the plant.

An analysis of the refined products and of the raw brine is given in Table II. It will be noted that the potassium chloride is comparatively free from borax. To obtain a product of this degree of purity has been one of the most difficult problems at the plant. A further operating difficulty has been the frothing of the evaporators, but this has been recently overcome. Improved operating methods, that will be made possible when the installation of new equipment is completed, will increase production and further improve the quality of the potassium chloride. About fifty tons of potash and twenty-five tons of refined borax is being produced per day. It is to be noted that the process depends entirely upon the use of artificial evaporation to obtain a concentrated brine.

SOLVAY PROCESS CO.

The borax claims of Searles and Skillings are controlled by the Pacific Coast Borax Co. This company and the Solvay Process Co. built a plant in 1916 and 1917 for the recovery of borax and potash from brine obtained from the salt body. The plant is now managed by the Solvay Process Co., and no authorized statements have been given out concerning the method of operation or the amount of production. The following outline of the process is believed to be correct: Preliminary solar evaporation of the brine is depended upon to give a solution of maximum concentration without the crystallization of potash salts in the ponds.

Further evaporation in multiple effect evaporators produces a hot concentrated potash solution from which a crop of KCl crystals is obtained. These are separated by filtration and the mother liquor is treated either with CO₂ gas directly or with SO₂ gas which breaks up the carbonates, giving CO₂ and sodium sulphite. The treatment converts the biborate into the less soluble metaborate, and borax crystals are obtained from the solution upon cooling. As contrasted with the process at Trona a less amount of fuel is required.

WEST END CHEMICAL CO.

The third plant to be established at Searles Lake is that of the West End Chemical Co., and the plant will become an active producer this year. The process uses less fuel than the two described, no use being made of artificial evaporation for producing a concentrated liquor. Brine is pumped from the crystal body to preliminary ponds, thence to secondary ponds for final concentration. When a solution of maximum KCl content is obtained it is pumped to a storage tank at the plant. Spray towers, shown in Fig. 4, are used to produce a crop of mixed crystals containing borax and potash. Spray towers are made of wooden frames covered with corrugated iron, and the solution is sprayed downward through 1-in. nozzles by pumps having a capacity of 12,000 gal. (45,000 liters) per minute. Recirculation of the liquor which drains from the deposited crystals recovers a large portion of the potash salts. About six tons of salts is produced per hour in the spray towers. The deposited salts are filtered, and dissolved in hot water, producing a hot concentrated KCl solution, from which crystals are obtained upon cooling. Borax is recovered from the mother liquor.

An optional method, which permits of winter operation, is as follows: A deposit of mixed salts is obtained during the summer months by solar evaporation in ponds about 3 ft. deep. These are harvested in the fall and winter, crushed and leached with hot water, KCl and borax being recovered as described.

BURNHAM PROCESS

All three of the plants at Searles Lake so far described use fuel oil for heating solutions or for evaporation and have a more or less expensive plant and equipment. The cost of fuel oil and interest on investment are important items in the cost of producing the marketable product. A fourth process is operated at Searles Lake, the distinctive feature being the use of solar evaporation only for the production of borax and potash. The process is the invention of G. P. Burnham.⁷ Advantage is taken of fractional crystallization at different concentrations and temperatures, and the brine is so manipulated that the various salts come down separately in different ponds. The rate of evaporation from brine at Searles Lake is about 6 ft. (1.83 m.) per year. The brine contains eighty tons of KCl and fifty tons of borax per acre-foot (5.0 and 3.7 kg. per cu.m. respectively), so that a 100-acre (40.5-hectare) pond evaporating continuously will deposit 48,000 tons of potash and 30,000 tons of borax per annum. (A 10-hectare pond evaporating continuously will deposit 1,080 metric tons of KCl and 677 metric tons of borax per annum.)

In the Burnham process several ponds are provided and the potash is made by flowing the brine into shallow ponds during the summer days, then into deep ponds

⁷U. S. Pats. 1,328,614, 1,286,932, 1,317,954, 1,321,282.

FIG. 5. HARVESTING PURE SALT FROM THE SURFACE OF "CRYSTAL BODY" AT SEARLES LAKE

at night, in order to retain the heat. By continuing the process warm evaporation is maintained until the brine becomes concentrated with KCl. At this point the brine is circulated between two shallow ponds, and cooling at night crystallizes out KCl in one pond and during the day further warm evaporation crystallizes out NaCl in the other.

Borax is made by flowing the brine into shallow ponds at night during the winter to cool, sodium sulphate and sodium carbonate being deposited. When the brine is coolest, in the early morning, it is flowed into deep ponds where the temperature is maintained for several days, borax gradually crystallizing out.

It was previously mentioned that the surface of the crystal body at Searles Lake was composed of quite pure sodium chloride. Salt is harvested by the American Trona Corporation, a special market existing for the product, which is entirely free from calcium and magnesium compounds. A spiked-tooth harrow is used to loosen the hard crust to a depth of about 2 in. and the salt is scraped into windrows by a road scraper. It is then shoveled into side-dump mine cars, a train of these being hauled alongside the rows from a narrow-gauge railroad by a tractor. The loaded train is returned onto the track by the tractor and hauled to the plant by a gasoline locomotive. The salt is dumped into storage piles and after air-drying is loaded into standard-gauge box cars for shipment.

In addition to potassium chloride, borax and salt, it would seem that sodium sulphate and carbonate could be obtained from Searles Lake brine, at least in crude form, and a market developed for the product for such uses as the manufacture of glass and paper pulp. It is a safe prediction that processes will be developed for the commercial production of all the salts contained in the brine of both Owens and Searles Lakes.

To establish a chemical industry in the heart of a desert is not a simple undertaking; housing, a complete commissary and other accommodations have to be provided for the workmen and living conditions made as comfortable as possible. An especially large stock of general supplies has to be carried on hand at all times, machine shop and other repair facilities have to be of the best. That successful operations are now conducted in these out-of-the-way places is to the credit of the men who have pioneered in the establishment of a new industry.

The writer wishes to acknowledge the courtesies extended by the management of the plants at Owens and Searles Lakes in gathering information for the preparation of this article.

The German Cement Industry

Howard W. Adams, representative of the Department of Commerce in Berlin, reports that the government operation of the German cement industry, put into effect on Jan. 1, 1917, was provisionally dispensed with on July 27, 1920, by an order issued by the Federal Ministry of Labor. This action was taken because the pressing demand for cement appeared to be satisfied, with a resultant diminution in sales. Bavaria, however, was excepted from the operation of this order. The government, through the Federal Commissioner for Cement, still retains jurisdiction over the fixing of prices for the domestic market.

COURSE OF CEMENT PRICES, 1914-1920

The price of cement in Germany at the outbreak of the war was 350 marks per 10,000 kilos (kilo = 2.2 lb.) for both government and private contracts. Following the establishment of government operation of the cement industry and the accompanying official regulation of prices there was a rapid rise in the cost of this commodity. The following prices per 10,000 kilos (f.o.b. mill and exclusive of packing) show the course of these prices since 1914:

Periods	On Government Contracts Marks	On Private Contracts Marks
August 1, 1914.....	350	350
January 1, 1917.....	430	430
October 1, 1918.....	735	760
April 1, 1919.....	885	910
April 1, 1920.....	3,991	4,061
August 1, 1920.....	3,330	3,400

INCREASE IN PRODUCTION

During the middle of last summer the production of cement was somewhat increased, due in part to the resumption of operations by the Offenbacher Portland-Zementfabrik (Gruppe der Portland-Zementwerke Heidelberg-Mannheim-Stuttgart) after lying idle for more than five years. The cement industry in Germany has not felt the effect of the coal shortage as much as other lines of manufacture for the reason that the mills were, to a considerable extent, able to use low-grade coal. Germany has resumed the shipment of cement to foreign markets.

RECENT PRICES FOR CEMENT

An idea of the recent domestic prices of German cement may be gained from the order issued Dec. 8, 1920, by the Federal Commissioner for Cement, with retroactive effect from Nov. 1, 1920, and extending to and including Jan. 31, 1921. According to this order the following prices are fixed for this period: For the district of the North German Cement Manufacturers' Association, 3,200 marks per 10,000 kilos (f.o.b. mill and exclusive of packing); the Rhine Westphalian Cement Manufacturers' Association, 3,100 marks; and for that of the South German Cement Manufacturers' Association, 3,300 marks. Proportionally lower prices are fixed for contracts for cement to be furnished the state governments for use in public buildings. The three sets of prices indicated above represent a considerable reduction over the prices fixed for the three months preceding Nov. 1, such reduction being to the extent of 200 marks, 300 marks and 100 marks, respectively. In this order of the government protection was provided the manufacturers against increases in the cost of coal during the Nov. 1-Jan. 31 period by allowing for an increase of 55 per cent.

Promotion of Scientific Research

Outline of a Program for Forwarding Research in the Chemical and Physical Sciences at the Universities —Industries Licensed Under Patentable Discoveries to Pay Reasonable Royalties for Support of Further Research—An Impartial Study of Facts

BY WILLIAM HOSKINS* AND RUSSELL WILES†

THIS plan is derived from the suggestions of several different people who have given attention to the subject, and an especial object has been to reconcile various conflicting views so as to conserve the interests of the public and of the universities to the fullest extent.

NEED OF UNIVERSITY RESEARCH

Initially, let us consider the ultimate object to be accomplished. It is probably not necessary to argue that an immense increase in scientific research is perhaps the most important future step for the welfare of this country. It is only by such research, commencing as pure science and ending as applied science, that production and therefore the physical well-being of the people can be materially increased without a corresponding increase in labor. Eminent members of university faculties have repeatedly called attention to the important need of a tremendous expansion of scientific research. Industry is taking care of the application of science, and will do so to a continuously greater extent as experience demonstrates the wisdom of industrial laboratories and as the universities turn out trained research men capable of solving the problem.

But if research in pure science is not correspondingly increased the stream will dry up at its source not only from lack of fundamental information but from lack of trained men. Industry cannot be expected to maintain pure science laboratories, as the maintenance of such a laboratory in an industrial organization is difficult if not impossible. It seems evident that the proper place for pure science research is in our universities, where the atmosphere is admirably adapted to lead the investigator to examine his facts without any commercial or industrial bias.

EXPANSION OF UNIVERSITY EQUIPMENT A SERIOUS FINANCIAL PROBLEM

However, the expansion of the physical faculties of physics and chemistry by the addition of the requisite number of research professors and the expansion of equipment for their use is a very serious problem. It has been estimated by eminent and experienced scientists that a man should remain in pure science research for ten years after receiving his doctor's degree in order to become a thoroughly trained, mature and competent worker. At the end of such a ten years' experience the industries will be entirely capable of taking care of these men and will need them in industrial laboratories where today it is almost impossible to obtain any competent help. During this ten-year period, however, a man must be paid a sufficient wage as a research professor to keep him from entering industry prematurely,

which means, as matters stand today, he probably must draw an average salary of \$5,000 a year. If the university is to produce any respectable number of men after a course like this, it is evident that the research department or division must become a very large and expensive institution, since to turn out ten men in chemistry and ten in physics per year after ten-year courses would require two hundred residents continually. This number could be doubled or trebled for a long time without saturating industry.

INDUSTRY MUST FINANCE

It has frequently been said that since in the end the discoveries in pure science will redound to the benefits of industry, therefore industry ought to finance the necessary expansion of the universities. It is, however, exceedingly difficult to secure this result in the usual way for several reasons. What is really meant by industry financing research is that a few large stockholders of industrial corporations shall finance research. Most corporations are not legally permitted to make donations direct to educational institutions. Under present methods our corporations are heavily taxed and the large stockholders are again heavily taxed on their depleted dividends so that there is little left for the universities. Besides it is a fact that the great bulk of small stockholders of corporations who profit by scientific research are never reached at all. The prime advantage of the present plan is that it enables payment to be made directly by industrial corporations in a legal manner and in proportion to the benefits derived by the corporations from scientific research and it permits the payments to be charged to expense so that they are free from burdensome income taxes.

RESEARCH WILL LEAD TO DISCOVERY

In the normal course of pure science, research made wholly without reference to any commercial end will inevitably discover novel processes, novel machines and novel compositions of matter, many of which ultimately become of the highest industrial importance and most of which can be patented because, in the eye of the law, they are patentable inventions. These inventions, being made without reference to a particular commercial end, are usually of the most broad and sweeping character and they frequently underlie whole groups of industries.

The industries which use these inventions produced in the universities as part of their regular work should pay for them out of corporate funds. It is reasonable that a very considerable income can readily be obtained in this manner without begging for charity, but as a matter of right. Most of our large corporations are glad and willing to pay liberally for anything which benefits them, especially if the proceeds are to be reinvested in furthering similar work, the advantage of

*Consulting chemist, Mariner & Hoskins, Chicago, Ill.

†Patent attorney, Drydenforth, Lee, Chritton & Wiles, Chicago, Ill.

which may later be reaped by the corporation. This result can be brought about through the patent system, and every objection so far suggested to the patenting of inventions by members of university faculties can be overcome not only technically but in spirit and substance.

PATENTS OPEN TO ALL

And it is of the utmost importance that these inventions should not be monopolized in one or a few hands, but should be freely offered to the public for all possible uses upon very reasonable terms. This can be done by letting it become known that such patents are not for sale, that no exclusive rights will be granted, but that anyone can have a shop right or license for his own purposes and his own plant upon the payment of a reasonable fee. This is precisely what has been done with the patents in the Cottrell process, which have been held by the Research Corporation. The process is used in a great number of industries for all sorts of purposes and industry is in nowise hampered by the patents, since everyone knows he may use them freely upon paying a reasonable price. As a result other inventors treat the Cottrell patent as if it were entirely non-existent except that they realize that a reasonable royalty must be added to the cost of operation. The point is, however, that no one attempts to avoid this patent or to get along without it, simply because it is held under these unusual conditions. We see, therefore, no reason why the public should be injured in the slightest degree by the grant of more patents held in a like manner. Indeed, from the standpoint of the public, it would probably be more advantageous to have inventions patented and the patents held open to general use upon payment of a reasonable royalty than to continue as at present.

PRESENT PRACTICE ENCOURAGES PIRATES

Today the practice of scientists is to present purely scientific papers dealing with laws rather than their application, and little or no mention is made of possible practical applications, even though these are more or less obvious. Almost immediately these papers are read by commercial investigators and the most evident practical applications are promptly patented. Thus neither the public, nor the inventors, nor the universities benefit, but in too many cases a small group of sharp-witted engineers secure the patents. In some cases these patents are invalid because the application of new truths is too obvious, but in others they are perfectly valid because the exceedingly abstract nature of the original thesis makes any concrete application of its principles patentable invention.

Furthermore, the thesis is written in a form unfamiliar to the Patent Office and the courts, and oftentimes fails to receive its full evidentiary weight in controversies affecting a subsequent patent. The public would be very much better off, and justice would be much more closely approximated in patent suits if, contemporaneously with the publication of a thesis, its substance were expounded in a patent drawn in the language familiar to the Patent Bar and the Federal Bench.

Furthermore, the existence of such patents would greatly enlighten the Patent Office and prevent the grant of numerous ill-advised patents which by reason of doubts as to their validity constantly embarrass industry. After a wide experience in patent matters and particularly those relating to chemistry, the authors are

satisfied that industry at large would be vastly better off if all discoveries were patented as fast as they are made providing only that a liberal policy was followed in licensing the use of these discoveries. There is at large a type of engineer commonly called a "patent pirate," who thrives by monopolizing the practical applications of the abstract discoveries of others. The patent pirate is a menace to industry and a parasite on the community. Nothing would so hamper his activities as to have the real discoverer take out broad patents in every case.

PUBLIC, NOT INDIVIDUALS, TO BENEFIT

It seems to be agreed that to permit members of the science faculties of our universities to patent their discoveries for their own personal benefit is an entirely wrong policy for several reasons. It tends to restrict directions in which research may be conducted by placing a premium upon lucrative lines of investigation; and worse still it tends to focus the attention of the investigator upon applied science rather than pure science and *pro tanto* causes the university laboratory to do work which ought to be done in an industrial laboratory. Any proposal, therefore, to meet the conditions of the problem must remove all thought of personal reward to the individual making the invention so that he shall remain in the same mental state as heretofore. This can readily be accomplished if it is understood that the inventions are to be assigned when the applications are filed and that all proceeds are to be applied to the expansion of research and general research facilities under the exclusive control of the head of the department.

On the other hand, the patenting of these inventions would have a highly beneficial effect in increasing the immaterial rewards of those engaged in research. Patents must issue in the name of the actual inventor and if the time ever comes when many of our great industries are paying tribute for the use of patents issued upon the inventions of our university faculties, industry will have driven home to it in a most forceful fashion the importance and value to a community of a trained research professor. Instead of being looked at askance by business as a cloistered theorist he will of necessity be respected as a builder of foundations. We all realize that our genuine scientists are too little appreciated by the community at large and there is no way in which the public judgment can be rectified so readily as by direct attack on the public pocketbook.

PLAN OF ORGANIZING THE PATENT WORK

It has been suggested that the universities would not desire in their corporate capacity to take over and own the patents negotiated for licenses and perhaps conduct suits. Possibly in the future this view might be changed and in a decade or two it might be understood that it was as much a part of the duties of the business manager to administer patent property as to administer real estate. It is supposed the university would accept the gift of a valuable patent the same as that of a piece of real estate, and would administer it in the same business fashion, and it might well be that in due time it would be appreciated that the business manager ought to administer this property the same as any other. However, initially, and if desired, permanently, there is no need for the university to appear in the matter at all. A few friends of the university having no connection with the board of trustees or with the faculty can

readily organize a trustee corporation not for pecuniary profit. These patents can be taken over by this holding company; it can grant the licenses, collect the royalties and pay over the proceeds to the university as a trust fund for the furtherance of research. In this respect the holding company would stand to the university precisely as does any other donor, would administer the patent property according to its best judgment and would turn over the proceeds without limitation as to the manner of expense by the university, or to be used in gifts for special purposes. If at any time the university should decide to administer the property direct, it could all be turned over to the university in its corporate capacity, but until that time the university would have no responsibility.

This leads naturally to the question of the manner of administration and the expense thereof. The ordinary investigator has no idea of the limits to which patent protection can extend and in most cases has no appreciation of the fact that he has made patentable inventions. Furthermore he is incapable by training and education of picking out the patentable from the unpatentable part of his work, so that this would have to be done for him by someone else. The only feasible arrangement is to have the papers, thesis and results of investigation reviewed by a patent counsellor sufficiently versed in chemical and physical matters quickly to grasp the situation, and to have counsel segregate the patentable matter and prepare and file patent applications. If the plan should succeed and an enormous research organization be built up, this work would require the services of several trained men, but the expense could be borne without difficulty by the holding company out of its proceeds, for the expense of drawing and soliciting patents would necessarily be an insignificant feature. In initiating the plan the work involved is relatively small, because relatively little research is being done. The comparatively insignificant government fees for patent applications can be taken care of by friends of the plan and of the university, without costing the university any money. If a plan of this sort should be generally adopted for universities, it would be quite feasible to secure the patent services of the alumni to an extent sufficient to make each of the plans become self-sustaining without expense.

CAUSE FOR LITIGATION REMOVED

As to patent litigation, there probably would be none. No case is known where a patent thrown open so that all the world could have it upon a payment of a reasonable royalty was deliberately infringed by manufacturing concerns. They all prefer to pay a royalty rather than to take chances of litigation. A few patents, usually on processes which can be practiced in every shop, have been extensively infringed even though licenses were cheap and available, but these cases have been exceptional in that each infringement was trifling in extent, but the number was very great. This occurred in the case of the driven well patent and some dental process patents where there were thousands of users of the invention. In the ordinary case the infringer has a more substantial interest in the invention and would prefer to be a licensee on reasonable terms. Furthermore the fact that the license fees would be paid over to an educational institution would lead industry to treat these patents most kindly and it would be surprising if litigation ever occurred. The Cottrell

patent above mentioned has never been litigated and doubtless never will be, because the fees are reasonable, are equal between like users and are applied to the furtherance of research.

FOUNDING SPECIAL RESEARCH FELLOWSHIPS

There are two other questions which have been thoroughly discussed, both involving the case where an outside party desires the university to undertake a particular piece of research and is willing to contribute to the expense, as by founding a fellowship. Of course at the outset it must be understood that the head of the department involved is to decide on the scientific lines only whether this piece of research is worth while, and he should not permit himself to be influenced by any commercial consideration. Sometimes the suggested line will be of great scientific value, and yet the investigation will be of the utmost commercial value to the donor. Inventions made in research under these circumstances will be of two kinds.

The first will be the rarer, where the donor of the fellowship is a skilled chemist or physicist himself and is able to direct the investigation in detail by suggesting specific things to be done. In this case the donor would be the true inventor, he having made the suggestion of definite procedure to be followed. Since, however, the facilities of the university are employed in the investigation, it would seem equitable that the university might insist upon a division of the proceeds, and it is suggested that in cases of this kind the university might properly insist that the inventions should be held for public use and that the proceeds be divided upon some fair basis. In one case now in the chemistry department of a university the donor of a fellowship has actually suggested and mapped out many of the experiments which have been made. He would have a legal right to patent these inventions in his own name and give the university nothing, but is perfectly satisfied to divide the proceeds equally, the university's share to be employed in the furtherance of chemical research. There seems to be no reason why the university should not accept such an arrangement, more particularly since it has now no rights whatever in the premises, and it certainly should not be hindered from making an interesting scientific investigation merely because the investigation is on the scientific truths underlying an invention or inventions already made by the donor.

In the more common case the donor of a fellowship would not have the scientific knowledge to map out the work in detail, but would only want a broad line investigated. Here the donor would not be legally the inventor, but the inventions, if any, would be those of the fellow or other investigator. Under those conditions an arrangement such as that offered by the donor above mentioned should be highly satisfactory. The question of the technical inventorship should not change the proposition and the donor of a fellowship should have a broad consideration in the commercial proceeds therefrom.

It is probable that as time goes on, if a broad plan works out, the research departments may not need to ask or accept fellowships at all, for after a decade or two of development the departments might be entirely self-sustaining. At the present time, however, when the departments are in serious need of expansion, it seems that the accepting of fellowships under these general conditions would be highly desirable.

Legal Notes

BY WELLINGTON GUSTIN

Verbal Promise by Salesman Not Binding, Especially When Promptly Repudiated

In a recent case where the Pocahontas Guano Co. had brought action against a dealer and another it was said the unauthorized contract of the company's salesman was ineffectual when promptly repudiated by the company.

The action arose out of a consignment of fertilizer to defendant for sale as agent of the company. Notes were given to the company in settlement of the fertilizer consigned to and sold by the agent. The agent testified on trial that he had sent the notes in a letter claiming that they were sent without prejudice to his right to recover damages for an alleged breach of a verbal contract made with him by a salesman of the Guano company to ship him another carload of fertilizer for his own use. By reason of the failure to do so he had sustained damages to his crop, for which he set up a counterclaim for damages against the company's suit for balance due in the notes. On trial the agent was given a verdict on his counterclaim, and judgment for the balance over the company's claim was entered. From this judgment the company appealed.

WRITTEN CONTRACT BARRED VERBAL PROMISES

The Supreme Court of North Carolina has reversed this judgment. It said there was not sufficient evidence to go to the jury in support of the counterclaim made by the dealer-agent. The contract between the company and the agent was in writing and was for shipment of fertilizer to be sold as agent. This contract contained the clause, "No verbal promises that conflict with the terms of this contract will be recognized by this company."

Subsequently to the above consignment the agent ordered another carload of fertilizer for his own use. The company did not ship, but sent its salesman to see the agent, who testified that he still had thirty or forty bags of fertilizer on hand which he had received as consignee and agent. He further testified that the salesman told him to sell these bags and he "would see that he got another carload."

On the other hand, the agent put in evidence a telegram and letter from the company and its salesman, acknowledging receipt of a telegram and letter from the agent, but stating that owing to prior orders the company was unable to accept the agent's order for another carload of fertilizer. The court said this showed a case where the defendant ordered a carload of fertilizer, which order the company declined to accept and fill. It did not appear from the evidence that it was in the scope of the agency of the company's representative to bind it to ship the fourth carload.

HIS ORDER REFUSED BY THE COMPANY

When he reported the order to the company he was promptly notified that the company could not accept and fill the order, and the agent was not misled by any reliance upon his order being filled. The court says he had no right to rely upon the unauthorized state-

ment of the agent, if made, that if he, the defendant, sold the thirty or forty bags which he had on hand for sale as agent, he "would see that a carload was shipped to the defendant for his own use." The contract defendant held showed no agreement was binding until countersigned by an officer of the company, and the company as well as salesman promptly notified the agent by letter and wire that owing to the scarcity of fertilizer and prior orders, his order could not be accepted.

Government Need Not Pay for Product It Destroys Under Act of Congress of March 4, 1915

In the case of the Great Western Serum Co. against the United States, decided adversely to the Serum company in the Court of Claims, the Supreme Court of the United States affirmed the judgment of the lower court.

The Serum company sued to recover the value of anti-hog cholera serum, anti-cholera virus and serum blood, seized without agreement to purchase by agents of the Bureau of Animal Industry in November, 1914, and thereafter destroyed.

The act provided that in case of an emergency arising out of certain contagious diseases of animals which threatened the live stock industry of the country the Secretary of Agriculture may expend the sum of \$2,500,000, then appropriated, "in the arrest and eradication of any such disease, including the payment of claims growing out of past and future purchases and destruction, in co-operation with the states, of animals affected by or exposed to, or of materials contaminated by or exposed to, any such disease wherever found and irrespective of ownership, under like or substantially similar circumstances, when such owner has complied with all quarantine regulations, and said sum shall be immediately available for the purposes specified."

The Supreme Court ruled that there was no purchase of the destroyed product or agreement therefor, and none was claimed, and that the act does not itself raise an implied contract by the United States to pay for the property so destroyed; and therefore an owner of materials contaminated by or exposed to such disease and destroyed by Government agents cannot sue for its value where there was no purchase or agreement to purchase the property destroyed.

Creditor's Knowledge Relieves Stockholder in Corporation From Liability Under Georgia Laws

In an action between the Farmers' Warehouse & Fertilizer Co. and the Macon Fertilizer Works the Supreme Court of Georgia has held that a creditor of a corporation who knows that the requisite amount of capital stock has not been subscribed may not proceed to collect a bill by an action against a subscriber, under the Georgia laws. The Civil Code (1910), section 2,220, says:

"Persons who organize a company and transact business in its name before the minimum capital stock has been subscribed for are liable to creditors to make good the minimum capital stock with interest."

Now the Supreme Court in this case has said that if at the time credit is extended the creditor knows the fact that the requisite amount of capital stock has not been subscribed, he cannot claim or be said to have been misled, and relatively to him the subscriber to the stock would not be stopped from pleading such knowledge as a defense to a suit based on the above section of the statute. (148 Ga., 388.)

Removal of Arsenic From Zinc Electrolyte by Means of Hydrogen Sulphide

This Article Describes Large-Scale Generation of Hydrogen Sulphide and Using It to Precipitate Arsenic From Electrolyte—The Acid Used for This Generation Is Completely Consumed and the Gas Is Completely Utilized in Precipitating Arsenic

By HERBERT R. HANLEY*

THE economical operation of an electrolytic zinc plant is partly dependent upon the practically complete removal from the electrolyte of all metals more electro-negative than zinc. Where these metals are present in relatively small amounts, this can be done by precipitation upon metallic zinc. Arsenic in the form of arsenites can be removed economically, if present not in excess of 1 or 2 g. per liter, by precipitation by means of lime as iron arsenate. If present in larger amounts, some other means must be depended upon, as the above-mentioned methods are then impractical. The problem of treating the arsenical zinc-fume which had accumulated at the Mammoth plant of the United States Smelting, Refining & Mining Co. at Kennett, Cal., for the recovery of zinc and cadmium presented a particularly interesting problem.

This bag-house fume when first collected contained the arsenic in the trivalent form as arsenites of the various metals. Because of the voluminous nature of the fume it was necessary to collect it under water. This resulted in the breaking down of the flocculent deposit that would otherwise be obtained. The coalescence of the solids produced a mud, or slime, of a normal specific gravity. During the storage of the bag-house mud a gradual oxidization of the arsenic occurred, with the result that after a few years' storage approximately half of the arsenic was present in the pentavalent condition. The solution of this mud in dilute sulphuric acid naturally produced a certain amount of zinc arsenate. This is soluble in slightly acid solutions at moderate temperatures; at temperatures above 60 deg. C., however, it coagulates, forming a gelatinous translucent precipitate, the completeness of the reaction varying inversely as the acidity. Also, if the slightly acid solution of zinc arsenate be neutralized with any base, there is obtained a very voluminous and gelatinous precipitate which cannot be washed free from soluble zinc salts. When solutions containing arsenates are treated with hydrogen sulphide for the precipitation of the arsenic, the consumption of this gas is uneconomical, a portion of the hydrogen sulphide being reduced to sulphur; in addition, this operation required an inordinate length of time.

These conditions make it impractical to consider the precipitation of the arsenic from this solution with hydrogen sulphide, and it is evident that for the economical recovery of the zinc some method must be devised whereby the losses entailed in the handling of the precipitates are avoided.

These difficulties practically disappear if the arsenic

be present in the trivalent condition: no insoluble compound of zinc and arsenic is formed during neutralization; the precipitate produced may be easily washed; the consumption of hydrogen sulphide is normal. Preliminary to the removal of the arsenic from the fume by means of hydrogen sulphide it became necessary to develop an economical process for the reduction of the arsenic to the trivalent condition.

This problem was solved in a practical manner by circulating the solution through a tower through which sulphur dioxide gas is passing. The tower is 2 ft. square, 30 ft. in height. The sulphur dioxide gas is produced by a pyrite burner. It was found that the reduction takes place in cold as well as hot solutions. This is probably due to the relative solubility of sulphur dioxide in hot or cold solutions of zinc sulphate. While the rate of the reduction may be greater in hot than in cold solutions, the greater solubility of sulphur dioxide in the latter accomplishes the reduction in approximately equal times under average conditions.

The reduction of 1,000 lb. of arsenic in the solution which contains about 10 g. of pentavalent arsenic per liter requires the pumping of this solution through the tower at the rate of 225 gal. per minute for sixteen hours. The consumption of sulphur dioxide is approximately 4.4 lb. per pound of arsenic reduced.

In Table I is shown a record of experiments in the reduction of the arsenic in the zinc sulphate solution

obtained upon leaching the bag-house fume with sulphuric acid. This solution contained approximately 6.0 g.p.l. H₂SO₄, 96.0 g.p.l. Zn, 4.0 g.p.l. Cd, 0.5 g.p.l. Cu and 8.9 g.p.l. As^v.

GENERATION OF HYDROGEN SULPHIDE

Two methods were considered for the generation of hydrogen sulphide: First, the distillation of oil with sulphur, a method formerly used for the production of

*Mining and metallurgical engineer, Bakersfield, Cal. Formerly superintendent, Mammoth electrolytic zinc plant, United States Smelting, Refining & Mining Co., Kennett, Cal.

asphalt from oil; and, second, the reaction of dilute sulphuric acid on low-grade copper matte. Under the local conditions which obtained at Kennett the sulphur-oil method proved to be more expensive and in general less promising of practical application than the sulphuric acid-copper matte process. With more favorable conditions the sulphur-oil method might, however, prove economical.

SULPHUR-OIL METHOD

In general, the sulphur-oil method consists in slowly distilling oil with sulphur at a temperature between 150 and 200 deg. C. To obtain maximum production of hydrogen sulphide from the sulphur it is necessary to use an oil of definite physical properties. If asphalt is to be made as a byproduct, the sulphur must not exceed 10 per cent the weight of the oil. The distillation of an oil with sulphur in excess of 10 per cent will, as a rule, produce a residue quite similar to coke. If the nature of the residue is immaterial, the amount of sulphur may be increased to 50 per cent of the weight of the oil with satisfactory results as regards

for the supply of an oil-residue with these particular characteristics.

SULPHURIC ACID MATTE METHOD

As is well known, hydrogen sulphide can be generated by the action of dilute sulphuric acid on the iron sulphide contained in matte. In order that this method may be used commercially it is not only necessary to obtain economical consumption of sulphuric acid but also necessary that the generating apparatus be safe in operation. A low-grade matte was available at Kennett of the following composition: Cu 10.0 per cent, Zn 3.5 per cent, Fe 54.0 per cent, S 28.0 per cent, insoluble 1.2 per cent, undetermined 3.3 per cent. In order to determine the ratio of the amount of acid consumed to the amount of hydrogen sulphide generated when this matte was treated with dilute sulphuric acid, seven 100-g. samples were treated with different amounts of acid, as shown in Table III. The residue was analyzed for copper, zinc and iron and the quantity of hydrogen sulphide liberated was determined.

The result of these tests brought out the fact that acid to the amount of 75 per cent of the weight of the matte is required to liberate the maximum quantity of hydrogen sulphide and that approximately 5.5 lb. sulphuric acid is required for each pound of hydrogen sulphide produced. Acid to the amount of 10 per cent of the weight of the matte is consumed by "acid-consuming" constituents of the matte before any hydrogen sulphide is liberated. This fact would make it economical to continue the treatment of the matte with acid until the maximum amount of hydrogen sulphide had been produced, varying somewhat due to local conditions.

RESISTANCE OF MATTE TO ACID TREATMENT

The treatment of matte with dilute sulphuric acid will not liberate hydrogen sulphide under all conditions. It was found that the physical condition of the matte, method of granulation, and the flux used in its production were factors that determined this characteristic. The results of investigations to control these conditions brought out the following facts:

- (1) High-grade mattes containing more than 20 per cent copper are usually active regardless of the furnace flux or the method used to reduce the matte to a granulated form.
- (2) Low-grade mattes containing about 10 per cent copper are usually active when the furnace flux consists of clean quartz, regardless of the method used to reduce the matte to a granulated form.
- (3) Low-grade matte containing about 10 per cent copper is usually inactive when the furnace flux consists of country rock, such as silicified rhyolite containing aluminum silicate. When this matte is granulated in water, however, it is active, but it loses this activity if allowed to become dry. This activity is retained indefinitely if the matte is kept immersed in water.

the yield of hydrogen sulphide. The maximum yield of gas is, however, not much in excess of 80 per cent of the theoretical obtainable from the amount of sulphur used.

RESULTS OF TESTS

The results of a series of tests are shown in Table II. The maximum conversion of 82 per cent of the sulphur to hydrogen sulphide in test 10 was obtained on a specially prepared oil. To obtain a similar yield in commercial-scale operation at the Kennett plant would have required co-operation with an oil-refining company

By meeting these conditions it was possible to keep on hand a dependable supply of matte for use in the generation of hydrogen sulphide.

APPARATUS FOR THE GENERATION AND USE OF HYDROGEN SULPHIDE

In the development of the process the apparatus used for the production of hydrogen sulphide consisted of a standard creamery churn, 4 ft. in diameter and 4 ft. in length, reinforced by the addition of double heads. The generator is supported on trunnions and may be rotated when desired. The gas outlet and the gas and acid inlet are inserted axially through stuffing boxes. The gas outlet pipe is connected to a Roots blower which delivers the gas to the precipitating tank. This tank is provided with a sealed top and pipes through which the gases may be circulated. The general layout of the apparatus is shown in Fig. 1. The matte is charged into the generator from the bin 1. Dilute acid is admitted from the storage tank 2, the amount of acid added being measured. A bin 7 is provided for the generator residue which is dumped into car 8 for disposal. The gas passes through a separator 4 to the Roots blower 11, which delivers the gas to the precipitating tank 16 through a perforated coil of pipe located about midway the depth of the tank, this particular location being important, as will be shown later. A blower 14 circulates a portion of the attenuated gas through the precipitating tank, delivery being at the bottom of the tank through a perforated coil of pipe, thereby causing a thorough agitation of the arsenical

FIG. 1. LAYOUT OF APPARATUS

solution. The impoverished gas which is forced through the solution in the precipitating tank by the blower 11 returns through pipe 9 and separator 5 to the generator. This arrangement is not only economical in the use of hydrogen sulphide but by preventing the escape of the gas to the atmosphere renders the operation safe. A drum 12 separates the froth from the gases. The circulation systems are closed except for safety seals 6 and 10 and a relief valve. These are located outside of the building. The generator operates under a slight vacuum which not only accelerates the generation of the

hydrogen sulphide but also assists materially in preventing its escape into the atmosphere of the room.¹

It was discovered that there would be a precipitation of zinc sulphide due to a local depletion of the arsenic in the solution if the gas from the generator was delivered to the blower 11 at the bottom of the precipitating tank. This precipitation of zinc sulphide is prevented by the delivery of the gas from the generator at the zone of maximum agitation caused by circulating the attenuated gas by means of blower 14.

DETAILS OF OPERATION

One thousand pounds of granulated matte is introduced from the storage bin through the manhole of the generator and the cover is closed. The blower 11 is started and 50 gal. of dilute sulphuric acid (200 g.p.l.) added from the tank, this amount being sufficient to take

FIG. 2. SOLUBILITY OF IRON IN SULPHURIC ACID

care of the initial consumption of acid. The addition of acid is then continued at the rate of about 50 gal. per hour, with an occasional rotation of the generator, until there is a diminution of the rate at which the gas is generated. The rotation of the generator causes the inert coating on the particles of matte to be removed by attrition, increasing the rate at which the hydrogen sulphide is liberated. When an amount of acid has been added which is calculated to liberate the maximum amount of hydrogen sulphide from the matte, the generator is rotated continuously until this acid is neutralized. The solution from the generator is removed by decantation and the matte residue dumped from the generator through the manhole.

IMPORTANCE OF USING DILUTE SULPHURIC ACID OF CORRECT STRENGTH

It is important that the dilute sulphuric acid be of such strength that complete neutralization will not form a saturated solution of sulphates at the operating temperature of the generator, otherwise a crystallization will take place within the generator. The formation of a saturated solution also causes a loss of acid. Dilute sulphuric acid containing 200 g. per liter will react with iron, producing a solution containing 120 g. iron per liter. This amount of iron in the form of iron sulphate is soluble in dilute sulphuric acid containing not more than 40 g. per liter, if the temperature of the solution is not less than 40 deg. C. This temperature is lower than the normal operating temperature of the generator.

The importance of using a dilute sulphuric acid of correct strength may be illustrated by the following example: Suppose the dilute acid contained 300 g. per liter H_2SO_4 . Referring to Curve B, this amount of acid will dissolve 170 g. of iron. Referring to curve A, it is

to be noted that a maximum of 145 g. of iron per liter is soluble in a solution containing no sulphuric acid. The difference between this maximum solubility and the amount of iron which would be dissolved by 300 g. of H₂SO₄ amounts to 25 g. iron per liter, which is equivalent to 43½ g. of sulphuric acid, and represents the amount which would be wasted if this strength were used.

PRECIPITATION OF ARSENIC

The precipitation of arsenic is accomplished in a solution containing not less than 10 g.p.l. H₂SO₄. This is necessary in order to prevent a simultaneous precipitation of zinc sulphide. The use of a more dilute solution is attended with an increasing precipitation of zinc sulphide; the use of stronger solutions not only results in the unnecessary loss of acid but also increases the amount of the precipitate produced upon the subsequent neutralization of this solution with lime rock and the expense necessary to handle it.

For the precipitation of one ton of trivalent arsenic there is required approximately 12 tons of matte and 4.5 tons of sulphuric acid. The matte residue will amount to about 8 tons and will contain practically all the copper of the original matte. The strength of the generator gas will vary between 0.5 and 8 per cent, depending upon the rate at which acid is added and also upon the activity of the matte.

Results obtained in treating the arsenical zinc solution are shown in Table IV. The amount of sulphuric acid used is calculated on the weight of arsenic precipitated, as this is the element which made necessary the treatment of the solution. Since the complete removal of the arsenic will cause the precipitation of zinc as sulphide, about 1 g. per liter of arsenic is left in solution. The precipitates obtained from lots 2 and 3 are high in zinc for this reason.

The arsenical precipitate is removed from the zinc solution by filtration. A plate and frame filter press is used, no difficulty being experienced in handling and washing the precipitate. It is uneconomical to wash the cake beyond the point where the water soluble zinc is less than 5 per cent.

REMOVAL OF LAST TRACES OF ARSENIC

The last traces of arsenic are removed by precipitation as an iron arsenic compound from a solution containing iron in excess of the amount required to form this compound, the precipitating agent being pulverized lime rock. This operation also results in the complete removal of the iron. The solution after the removal of the iron precipitate by filtration is given the usual treatment for the removal of cadmium and traces of other metals which may have escaped the previous treat-

ments. It is to be noted that the complete removal of cadmium with hydrogen sulphide is impracticable, since it is necessary to perform this precipitation in a nearly neutral solution, in which case there is simultaneous precipitation of zinc. The cadmium is removed by filtration and the solution delivered to the electrolytic zinc cells. The zinc cathodes produced are of excellent quality.

Generators holding 8 tons of matte have been designed, and consist of cylindrical wood drum, lead lined, and with an inner wood covering to protect the head from abrasion. This is supported in a manner similar to revolving driers, with circular track and bearing wheels.

This apparatus was operated over a period of ten months with satisfactory results; there were no accidents due to the use of hydrogen sulphide and no deleterious effects experienced by the workmen in or about the plant. This demonstration of the practical use of hydrogen sulphide in large-scale work may open up new fields of usefulness, removing this gas from the class of laboratory reagents. There is a possibility of its use for the sulphide coating of ore particles preliminary to recovery in flotation machines and as a reagent to assist in the selective flotation of complex ores. Its more extensive use in the chemical and metallurgical field may come about as a result of the success of this installation.

San Francisco, Cal.

Preparation of Pure Platinum

It is reported that the Bureau of Standards has recently succeeded in producing platinum of higher purity than any obtainable from the platinum dealers in this country or abroad. The "normal thermo-element platinum" of W. C. Heraeus has long been accepted by scientific laboratories as the standard for use in platinum resistance thermometers, thermocouples and other equipment requiring platinum of the highest possible purity. The platinum prepared by the bureau appears to be of a better quality than the best of the Heraeus wire to which the bureau has had access.

It was found that the Heraeus platinum, although free from other platinum metals and the usual base metals, contains small amounts of calcium. By careful control of the operation of melting, which is usually done on lime, the bureau has prepared platinum containing no more than a trace of this element. It was noted also that calcium, even when present in very small quantities, has a considerable effect upon certain of the physical properties of platinum.

The bureau purposes to make a further study of the best conditions for melting platinum on lime and will also investigate the suitability of other refractories.

Synthesis of Chlorine-Free Benzoic Acid From Benzene—II

Influence of Reaction Conditions on the Yield of Benzonitrile in Fusions of Benzene Sulphonate and Sodium Cyanide—Variation in Composition of Charge, Reaction, Temperature and Pressure*

BY RALPH H. MCKEE AND FRANK A. STRAUSS

THE chief conditions capable of variation in the benzonitrile reaction are: The composition of the charge, the reaction temperature, and the pressure.

The composition of the charge may be varied in three ways: By changing the proportion of cyanide to sulphonate, by the substitution of salts other than sodium salts, by the addition of other substances to the charge. All three methods of variation were investigated.

CHANGES IN THE RATIO OF CYANIDE TO SULPHONATE

The original method of Merz makes use of equal parts of cyanide and sulphonate. As the theoretical ratio is 1 part NaCN to 3.67 parts $\text{NaSO}_3\text{C}_6\text{H}_5$, it will be seen that Merz' mixture contained a large excess of cyanide. As the cyanide is the more expensive constituent, it is important to limit its use as much as possible.

A series of runs was made in which the proportion of cyanide to sulphonate was varied. The results are given in Fig. 3.

The experiments indicated the following general relations:

When cyanide is in excess, the time of reaction is

FIG. 3. EFFECT OF VARYING RATIO
NaCN : $\text{NaSO}_3\text{C}_6\text{H}_5$

practically independent of the composition of the charge. When sulphonate is in excess, the time of reaction increases approximately in proportion to the added sulphonate.

The yield of benzonitrile based on sulphonate de-

creases progressively as the proportion of sulphonate increases.

The yield of benzonitrile based on cyanide at first increases as the proportion of cyanide increases. It reaches a maximum with equimolecular proportions and after that falls off slightly.

The yield of volatile sulphur compounds and tar

FIG. 4. ANALYSIS OF RETORT RESIDUE

is a maximum when equimolecular portions are employed. The figures are somewhat irregular because of the difficulty of collecting the tarry residue quantitatively.

These results may be interpreted somewhat more satisfactorily with the aid of the analyses in Table II.

TABLE II. ANALYSES OF RESIDUES FROM RETORT

	Temperature 430 deg. Atmospheric Pressure		
	Ratio Cyanide: Sulphonate		
	1:3.00	1:3.75	1:6.00
Na_2CO_3	49.9	54.2	8.4
Na_2SO_4	2.5	2.5	1.9
Na_2SO_3	1.2	2.1	19.1
Na_2S	10.7	7.2	0.3
NaCNO	1.9	1.0	1.3
NaCNS	12.4	3.8	1.0
NaCN	0.0	0.0	0.0
$\text{NaSO}_3\text{C}_6\text{H}_5$	1.9	3.9	50.2
Insoluble (carbon).....	18.5	27.9	9.9
$\text{Na}_4\text{Fe}(\text{CN})_6$			1.7
FeO			1.0
	98.9	102.6	94.8

The variations in the principal components of the residue are plotted in the form of curves in Fig. 4.

From a study of the curves, the following conclusions may be drawn:

*For Part I see CHEM. & MET. ENG., vol. 24, No. 15, p. 638, April 13, 1921.

The products of reduction—sodium carbonate, sodium sulphide and sodium thiocyanate—are formed in smaller proportion as the proportion of sulphonate increases.

The percentage of sodium sulphite, the normal product of the benzonitrile reaction, is small when cyanide is in excess, but increases rapidly as the excess of sulphonate increases.

The percentage of insoluble (carbon) first increases and then decreases as the proportion of sulphonate increases, paralleling closely the curve for sulphur compounds and tar in the distillate. This indicates that the carbon and the sulphur compounds and tar are formed by the same action—namely, by pyrogenic decomposition, or “cracking.”

As long as an excess of cyanide is present the sodium benzene sulphonate in the mixture is decomposed almost completely. When an excess of sulphonate is present, however, a large amount will be found undecomposed in the residue. The excess sulphonate serves largely as a diluent, and this dilution seems to result in a smaller amount of undesired reduction and decomposition. The full significance of this dilution will be shown when the effect of temperature is considered.

Taken together, these results indicate that when cyanide is in excess the predominating side reactions are those due to its reducing action; as equimolecular proportions of the reacting material are approached, thermal decomposition becomes the predominant side reaction; while when an excess of cyanide is present the excess serves as an inert diluent and side reactions are repressed to a considerable extent.

THE USE OF SALTS OTHER THAN SODIUM SALTS

It is possible to effect substitutions for either the sodium benzene sulphonate or the sodium cyanide in the charge. Both types of substitutions were tried.

As substitutes for sodium benzene sulphonate, the sulphonates of potassium, ammonium, the alkaline earths and the heavy metals suggest themselves. Potassium salts, because of their high price at the time of this investigation, would not be considered as a commercial possibility. The alkaline earth sulphonates almost invariably give smaller yields in this type of reaction.

The ammonium salt melts at a relatively low temperature.¹² For this reason it was thought that it might react with sodium cyanide at a low temperature. However, double decomposition was found to take place, volatile ammonium cyanide being formed, which sublimed out of the retort, leaving sodium benzene sulphonate behind. Lead, copper and zinc benzene sulphonates were found to decompose at low temperatures.

As substitutes for sodium cyanide, potassium cyanide and the ferrocyanides suggest themselves. The cost of the potassium salt again limited its possibilities. Sodium ferrocyanide, however, is cheap and would have the advantage over the simple cyanide of being relatively non-hygroscopic and non-poisonous.

A mixture of anhydrous sodium ferrocyanide and sodium benzene sulphonate was heated in the retort in the usual manner. No distillate appeared until the temperature within the retort reached 455 deg. At this temperature a small amount of oil came over, but on examination it was found to contain not more than a trace of benzonitrile. As this is about the tempera-

ture at which sodium benzene sulphonate begins to decompose,¹³ it is evident that sodium ferrocyanide is non-reactive at this temperature.

Because of this unforeseen result, the work of Witt¹⁴ was repeated. A mixture of 56 g. anhydrous potassium ferrocyanide and 144 g. sodium benzene sulphonate were heated to 430 deg. in the retort in the usual manner. The reaction took place as usual, but the yield of the benzonitrile was small (24.4 per cent based on sodium benzene sulphonate). The marked difference between sodium and potassium ferrocyanides in this reaction is interesting.

THE ADDITION OF OTHER SUBSTANCES TO THE CHARGE

In all these runs the mass was apparently never in actual fusion during the reaction, but only sintered at the temperatures attained. It was believed that if the mass could be made to assume the liquid state, better yields could be obtained.¹⁵ As has been shown, the use of easily fusible salts is not possible in this reaction. It seemed possible that the same results could be obtained by adding to the charge a third component which would lower the melting point of the mixture. Unfortunately there are few cheap salts of low melting point which will not react with one of the components of the charge. Sodium thiocyanate is satisfactory in this respect. However, the addition of sodium thiocyanate did not lower the reaction temperature and caused no appreciable change in the benzonitrile yield. The thiocyanate rendered the mass somewhat more fluid during the reaction, but on laboratory scale this was a disadvantage rather than an advantage, as the pasty mass resulting tended to clog the delivery tube of the retort. The addition of sodium hydroxide to the charge was found to cut down the benzonitrile yield appreciably, as might be expected.

Results from runs with a large excess of sulphonate indicated that good results might be expected from the addition of inert diluting material. As a diluent, common sand was selected on account of its cheapness and inertness. A discussion of the runs with added sand is postponed until the effect of temperature has been considered.

THE REACTION TEMPERATURE

A series of runs under varying temperature conditions was made, using a mixture of cyanide and sulphonate 1:3 by weight. This proportion was found to be a convenient one, giving good yields with a short reaction time. The results of these runs are summarized in Fig. 5.

It will be seen that the reaction time decreased rapidly as the temperature increased. It was found that no reaction took place below 410 deg. Below 420 deg. it took place too slowly for definite measurement. The yield of benzonitrile fell off as the temperature increased above 430 deg. Thus temperature control within a narrow range is necessary to get good yields. The variation in yield of sulphur compounds and tar is of no special significance.

Fig. 6 shows the logs of the above runs plotted in the form of curves. The inside temperature of the retort, the outside temperature and the rate of distilla-

¹⁵*Cf.* also the work of Reid [*Am. Chem. J.*, vol. 43, p. 162 (1910)]. He investigated the formation of benzonitrile by the distillation of mixtures of benzoates and thiocyanates, and found that the use of easily fusible salts gave greatly increased yields.

¹²256 deg., Norton *J. Am. Chem. Soc.*, vol. 19, p. 835 (1897).

tion have been plotted against time for each run. Only the first part of the log of each run is shown.

These curves are typical of a strongly exothermic reaction. In each case the inside temperature rose steadily until a point in the neighborhood of 410 deg. was reached. Here the reaction took place more rapidly so the heat liberated could be conducted away. Consequently the inside temperature rose above that of the heating bath. At the same time the evolution of gas and fume (volatile ammonium salts), which up to that time had been negligible, took place with great rapidity. The rush of gases in the case of the run at 440 deg. was so vigorous that the stoppers were blown out of the collecting train, and because of the violence of the

20 deg. The actual heat of reaction at 420 deg. will, of course, differ slightly from this value. A rough calculation will show that this small heat effect is not sufficient to account for the marked temperature rise. The side reactions, therefore, must be responsible for a part of this unforeseen phenomenon. For example, the reaction:

is quite strongly exothermic. It has already been shown that this is probably one of the side reactions. The oxidation of sodium cyanide to the cyanate by sodium benzene sulphonate is, no doubt, also exothermic. Hence the heating effect observed is not due to the main reaction alone, but to undesired side reactions as well.

THE EFFECT OF ADDITION OF INERT MATERIAL

It is clear that the rise in temperature noted during the reaction is detrimental to the formation of benzonitrile, since, as has been shown, the yield falls off with increasing reaction temperature. The true significance of the effect of an inert diluent on the reaction now becomes apparent.⁷⁸ The dilution material can check the undesired temperature rise in two ways: By its heat capacity, and by improving the thermal conductivity of the mass, which normally is low.

A number of runs were made with added sand, using two different ratios of cyanide to sulphonate and varying proportions of sand. The results are given in Fig. 7. The addition of sand to the mixture at first caused an increase in the benzonitrile yield, as was predicted. The yield, however, attained a maximum with the addi-

FIG. 5. EFFECT OF TEMPERATURE CHANGE.
RATIO NaCN : NaSO₃C₆H₅ :: 1 : 3

reaction it was not thought advisable to go above this temperature. Simultaneously the rate of distillation, especially in the run at 440 deg., increased greatly.

These temperature curves are exactly similar to those obtained, for instance, on heating an alloy showing a "reaction point." The temperature at which the exothermic effect occurred was practically constant at a value close to 410 deg., which was previously found to be the minimum for the reaction. The reaction temperature may, therefore, be definitely fixed at 410 to 415 deg.

The heat of the benzonitrile reaction may be calculated from the data in the literature.⁷⁶ Following the usual notation,⁷⁷ the reaction may be written:

The reaction, therefore, is exothermic to the extent of 4.4 large calories, based on thermochemical data for

FIG. 6. EFFECT OF TEMPERATURE CHANGE

tion of about 70 per cent sand. These results indicate that the course of the reaction is influenced by several factors. In the first place, the sand dilutes the reaction mixture and lowers the undesired temperature rise, thereby increasing the yield. On the other hand, by dispersing the particles of the reacting materials, the

sand renders contact between them less intimate and thus decreases the yield. The surface of the diluent probably has an influence as well; the benzonitrile vapor on coming in contact with the heated surfaces of the sand particles undergoes pyrogenic decomposition.

With proportions of sand up to 70 per cent the increase in yield due to dilution overbalances the

FIG. 7. EFFECT OF ADDITION OF SAND

unfavorable effects of the increase in surface and volume. Above this point, however, these unfavorable characteristics more than offset the beneficial influence of additional dilution, and the yield decreases.

EFFECT OF REDUCED PRESSURE

A run was made in which the pressure within the retort was maintained at 120 (± 5) mm. mercury, absolute pressure, by means of a suction pump. The reduction in pressure was found to make no change in the minimum temperature of the reaction. The results are given in Table III. A run at atmospheric pressure is included for comparison.

These results indicate that lowering the pressure favors the formation of sulphur compounds and tar at the expense of benzonitrile. As the formation of sulphur compounds is accompanied by the simultaneous liberation of large quantities of gaseous products, this result is in accord with Le Chatelier's theorem, the reaction taking place with the greatest increase in volume being favored by reducing the pressure. Hence the use of reduced pressure is undesirable.

In summing up the above results, it may be stated that the most favorable conditions for the benzonitrile reaction have been shown to be: Temperature 420 to 430 deg.; atmospheric pressure; cyanide and sulphonate in equimolecular proportions, or a slight excess of cyanide; the addition of a certain amount of inert material. For 40-mesh sand, the optimum quantity for

addition is 70, per cent, for other inert materials the amount to be added would probably differ.

THE USE OF LOW-GRADE COMMERCIAL CYANIDES

A number of processes which utilize atmospheric nitrogen in the manufacture of alkali cyanides have been developed. At least two of them are now being operated on a commercial scale. Since these processes are possible sources of cheap cyanide, it was thought advisable to determine the applicability of such material to the benzonitrile reaction.

Cyanide prepared from calcium cyanamide by heating with salt and carbon is being manufactured in large quantities and has proved a satisfactory substitute for the purer material for many purposes. Such "sodium cyanide" is relatively impure, containing 25 to 60 per cent NaCN equivalent, the remainder consisting of other sodium salts, calcium salts, carbon, etc.

TABLE III. EFFECT OF PRESSURE

Ratio NaCN : $\text{NaSO}_3\text{C}_6\text{H}_5$: : 1 : 3.00 by weight; temperature 430 deg.		
	Absolute Pressure	mm. Mercury
	760	120
Benzonitrile.....	39.0%	37.5%
S compounds and tar.....	9.7%	14.6%
Yield based on sodium benzene sulphonate		

A sample of this cyanide was obtained which was stated by the makers to have approximately the following composition: NaCN 30 per cent, NaCl 4 per cent, CaCl_2 35 per cent, CaO 13 per cent, remainder carbon and undetermined. The material was in the form of gray, flaky fragments.

A mixture of this material and sodium benzene sulphonate, in the ratio NaCN: $\text{NaSO}_3\text{C}_6\text{H}_5$ of 1:3, was distilled in the usual manner. A yield of only 11.7 per cent benzonitrile (based on $\text{NaSO}_3\text{C}_6\text{H}_5$) was obtained. Apparently the cyanide in this material is in a form not readily available for the reaction, or perhaps the impurities present, especially the large amount of free

FIG. 8. STILL IN USE IN LARGE-SCALE EXPERIMENTS

lime, affect the yield unfavorably. As already stated, the addition of a small amount of sodium hydroxide

¹⁰Landis, Trans., Am. Electrochem. Soc., vol. 37, p. 87 (1920).

caused a large decrease in yield. Calcium oxide might well have the same effect. According to Landis, the cyanide is present as the calcium salt rather than as sodium cyanide.

EXPERIMENTS ON A COMMERCIAL SCALE

During the course of this work the apparatus shown in Fig. 8 became available for large-scale experiments. It consisted essentially of a beta-naphthol still of the usual type (capacity about 300 gal.) modified by the addition of a stirrer with two scraper arms set close to the bottom of the still. The still was set in brickwork and heated by a coke fire. A pyrometer was fixed in the hollow shaft of the stirrer. Reduced pressure could be maintained if desired. Although this equipment was clearly not well adapted to carrying out the reaction, it was thought that some information might be obtained by its use.

Commercial 96 to 98 per cent sodium cyanide and high-grade sodium benzene sulphonate specially dried were used. No machinery was available for grinding and mixing the components of the charge, so it was necessary to use the coarse materials and trust to the mixing action of the stirrer in the still.

In one run a mixture of several hundred pounds of cyanide and sulphonate in equimolecular proportions were charged into the still and the temperature raised. Temperature control was difficult, and the indications of the pyrometer were of little value. When the reaction began it was propagated through the mass with great violence. The gases evolved were not able to escape through the offtake pipe and receiver fast enough, and the pressure within the still rose, finally blowing out the packing between the cover and the body of the still and allowing large quantities of gases to escape. The distillate which collected in the receiver consisted mainly of sulphur compounds, as might be expected from the high reaction temperature.

In other runs attempts were made to feed the reaction mixture into the hot still in small quantities. Runs were also made in which one of the components was placed in the still and the other added gradually. These experiments were unsuccessful, partly because of mechanical difficulties, and partly, no doubt, because intimate mixing could not be secured. This work was carried out before the favorable effect of dilution had been demonstrated in the laboratory. No large-scale experiments using diluents were made.

This work showed conclusively that apparatus of the type used is absolutely unadapted to carrying out the reaction on a large scale. For successful operation, intimate mixing, accurate temperature control and means for dissipating the heat of the reaction are necessary.

HYDROLYSIS OF BENZONITRILE

Many workers have investigated the hydrolysis of nitriles in the past. Both acid and alkaline solutions have been employed. Although physicochemical studies⁸⁰ of the reaction velocities indicate that, in the cold, hydrolysis by dilute alkalis is more rapid than by dilute acids, it has generally been found that warm moderately concentrated acids give more rapid and more complete hydrolysis than aqueous alkaline solutions.⁸¹

From a commercial standpoint the use of acid seems

the more advantageous. If, for instance, sulphuric acid is used, the products of the reaction are free benzoic acid, and ammonium sulphate, which remains in solution. The benzoic acid may be recovered by steam distillate, while the acid ammonium sulphate solution may be circulated through a scrubber to absorb the ammonia in the gases from the benzonitrile still, after which the ammonium sulphate content may readily be recovered. If caustic soda solution is used as the hydrolytic agent, an absorption system must be employed to recover the ammonia evolved. Moreover, the resulting sodium benzoate solution contains an excess of alkali and other impurities, which prevent its direct evaporation for the production of sodium benzoate. Hence it must be acidified to precipitate out benzoic acid, thereby necessitating a considerable expenditure of acid and alkali.

EXPERIMENTAL WORK ON HYDROLYSIS

It was found that benzonitrile could be hydrolyzed smoothly and rapidly by heating with 2.5 to 4 times its volume of sulphuric acid, sp.gr. 1.60 to 1.66 (54 to 59 deg. Bé.; 68 to 74 per cent H_2SO_4). In fact, the reaction when once started proceeded spontaneously from its own heat. It was necessary to add the benzonitrile to the hot acid gradually when large amounts were hydrolyzed.

In order to determine the efficiency of this method of hydrolysis, a weighed sample (2 g.) of re-distilled benzonitrile (b.p. 190 to 191 deg.) was heated with 20 c.c. sulphuric acid (sp.gr. 1.6) in a flask with reflux condenser for thirty minutes. The flask was cooled, contents diluted, and extracted with four 10 c.c. portions of ether. The ether extract was washed with several small portions of water to remove traces of sulphuric acid, transferred to a tared flask, the ether distilled off, and the residue weighed. A weighed portion of the residue was then titrated with fifth-normal sodium hydroxide previously standardized against Bureau of Standards benzoic acid.⁸² A yield of 95.2 per cent of theory was obtained. It is probable that the actual conversion of benzonitrile into benzoic acid was nearly quantitative, and that the deficiency of 4.8 per cent was due mainly to losses inherent in the method of analysis, loss by incomplete extraction, by washing the ethereal solution with water and by volatilization of benzoic acid on distilling off the ether.

A sample of the crude benzonitrile as obtained by steam distillation was next analyzed in the same manner. A benzoic acid yield equivalent to 90.4 per cent of theory was obtained. Assuming again a loss of 4.8 per cent in analysis, the crude benzonitrile contained 94.7 per cent C_6H_5CN , a figure which confirms the results of fractional distillation.

These results indicate that hydrolysis by sulphuric acid is a rapid and efficient method of converting benzonitrile into benzoic acid. On a large scale the losses ought to be small, and a conversion efficiency of around 95 per cent ought to be readily obtainable.

A larger quantity of crude benzonitrile was next hydrolyzed in order to determine the purity of the resulting acid. The benzonitrile was allowed to flow drop by drop into 2.5 times its volume of hot sulphuric acid, sp.gr. 1.6 (54 deg. Bé.), contained in a flask provided with a reflux condenser and a stirrer. Flask and contents were maintained at 125 to 140 deg. during

⁸⁰Von Peskoff and Meyer, *Zeit. phys. Chem.*, vol. 82, p. 129 (1913).

⁸¹For a summary of methods of hydrolysis see Sudborough, *J. Chem. Soc.*, vol. 67, p. 601 (1895).

⁸²Morey, *Bull. Bur. Standards*, vol. 8, p. 643 (1913).

the addition of the nitrile and for thirty minutes thereafter. The contents were then subjected to steam distillation, and the beautifully crystalline benzoic acid filtered out of the cooled distillate.

A sample of this acid dried over concentrated sulphuric acid had a slight odor, a faint yellowish tinge, m.p. 121 deg. Its C_6H_5COOH content by titration was 99.67 per cent. A 2-g. sample was burned in a calorimeter bomb in the usual manner. The bomb washings showed only a faint opalescence with barium chloride, indicating that the acid was practically sulphur free. It was, of course, free from chlorine. By subliming this acid, or by dissolving it in alkali, re-precipitating and re-crystallizing from water, pure white samples, practically odorless, were prepared.

DISCUSSION OF RESULTS

Some estimate can now be made of the commercial possibilities of the proposed process. The table gives the cost of the principal raw materials per hundred pounds of benzoic acid for the commonly used benzyl chloride-bleach process and for the nitrile process. Comparison is made with the bleach process because this is the one at present in most common use. The prices of all materials except sodium benzene sulphonate are those current May 1, 1920. Sodium benzene sulphonate is not ordinarily quoted in the market reports, but sales are known to have been made at this date at the figure given. Present prices for delivery on contracts would be lower for every item.

RAW MATERIAL COST PER 100 LB. BENZOIC ACID	
Benzyl chloride-bleach process:	
143 lb. toluene at 4c.....	\$5.72
143 lb. chlorine at 6c.....	8.58
149 lb. bleaching powder at 4c.....	45.60
Cost per 100 lb. benzoic acid.....	\$59.90
Proposed nitrile process:	
330 lb. sodium benzene sulphonate at 7c.....	26.60
104 lb. sodium cyanide (96-98%) at 24c.....	24.96
Cost per 100 lb. benzoic acid.....	\$51.56

The quantities assumed for the benzyl chloride-bleach process are those actually employed in large-scale manufacture. Calculations for the nitrile process are based on a nitrile formation efficiency of 43 per cent and 90 per cent efficiency on hydrolysis. The cost of the acid required for hydrolysis has not been included, and no credit has been allowed for the ammonium sulphate formed as a byproduct. Assuming 70 per cent recovery of the nitrogen content of the cyanide used, a conservative figure, about 1 lb. of ammonium sulphate would be recovered for every pound of benzoic acid produced. At the present quoted price of ammonium sulphate this would far more than pay for the acid required.

These figures, of course, do not take into consideration manufacturing costs. In the case of the nitrile process no data are available on which to base an estimate. There is no reason to believe, however, that manufacturing costs of the two processes would differ greatly.

The nitrile process might perhaps labor under a certain handicap because of the highly poisonous nature of the cyanide used. Accidents in the other industries employing cyanide are infrequent, and with proper precautions accidents ought not be feared. A distinct advantage of the process would be the purity of the product, as benzoic acid free from chlorine commands a premium of 10c. a pound over the ordinary acid.

It is, however, in connection with the future of the cyanide industry that the proposed process appears most interesting. The problem of cheap cyanide has been attacked with great vigor in recent years, and with striking success. The price of sodium cyanide has been declining steadily for some time, and increases in production and improvements in methods of manufacture will probably cause a further drop. As production has increased, new uses for cyanide have been sought. Its use in the manufacture of organic chemicals has been proposed, but up to the present no appreciable amount has been employed in this branch of the industry. The proposed process, however, might well offer a profitable means of utilizing some of the surplus cheap cyanide produced by improved methods.

SUMMARY

A process for the manufacture of benzoic acid from benzene has been outlined and studied in detail. The mechanism of the reaction and the nature and extent of the side reactions have been investigated. The effect of variations has been studied and the optimum conditions for the reaction have been established.

The results of the experimental work indicate that, with a source of cheap cyanide, the process proposed would produce benzoic acid of a higher degree of purity than the bulk of the acid on the market today at a cost below that of the present methods of manufacture.

Record Production of Borax in 1920

The quantity of borax produced and sold in the United States in 1920 was 35,280 short tons, valued at \$5,674,000, according to R. C. Wells, of the United States Geological Survey. This is a record production and value, exceeding even those of 1919—28,518 tons and \$4,351,891—which were higher than those of any previous year.

For many years borax has been manufactured in the United States from the mineral colemanite, a calcium borate, which is mined in California, but for the last two years some borax has also been obtained from the water of Searles Lake, California, as it is one of the salts that the brine yields by a certain method of treatment. This method of treatment marks a new departure in the borax industry and recalls the old days in the '60s when borax was made by recrystallizing the crude salt found in the mud of Borax Lake.

The total quantity of crude borates produced in the United States in 1920 amounted to 120,320 tons, valued at \$2,173,000. This is a record in quantity, though not in value, on account of the lower grade of the ores.

Borax is used in large quantities in making the enameled coating for cast-iron and steel ware used in plumbing fixtures, chemical equipment and kitchen utensils. It is also a constituent of borosilicate glasses, such as are employed in making lamp chimneys, baking dishes and laboratory glassware. Considerable borax is also used in the laundry and kitchen, in making soap and starch, in paper sizing, and in tanning and welding.

In the United States a considerable quantity of boric acid is made from borax as well as from colemanite. Boric acid is an antiseptic and is also used in cosmetics. It is also employed to preserve meats under conditions permitted by the food and drugs act.

Microstructure of Chromium Steels

Brief Review of the Literature, Especially From the Japanese Investigator Murakami, Presenting a Structural Diagram, Micrographs and an Explanation of the Changes in Transformation Temperature Following Various Reheatings

IN AN early investigation of the effect of chromium in steels Osmond¹ concluded that this element might exist in a state of solid solution in iron, as a compound of chromium, iron and carbon, or as a solid solution of the compound in iron. From his microscopic examination of two series of chromium steels Guillet² reported three types of structure—i. e., pearlitic, martensitic or troostitic, and double carbide, these differences being known to depend upon the thermal treatment. Double carbides of chromium and carbon have been reported by other investigators, though no formulæ have been agreed upon. By heating metallic chromium and carbon in an electric furnace Moissan³ obtained two carbides, Cr_3C_2 and Cr_4C .

Likewise Williams⁴ obtained a double carbide, $3\text{Fe}_3\text{C} \cdot 2\text{Cr}_3\text{C}_2$ by using a mixture of chromium oxide, iron and petroleum coke. Carnot and Goutal⁵ obtained chemically the residues $\text{Fe}_3\text{C} \cdot 3\text{Cr}_3\text{C}_2$ from a ferrochromium and $3\text{Fe}_3\text{C} \cdot \text{Cr}_3\text{C}$ from two chromium steels. Arnold and Read⁶ also carried out an extensive investigation of iron:carbon:chromium alloys and by analyzing the residues obtained by electrolysis (experimenting upon well-annealed samples containing 0.64 to 0.85 per cent carbon and 0.65 to about 24 per cent chromium) concluded that in steels containing less than 10 per cent chromium this element exists as carbides Cr_3C_2 or Cr_4C and forms an isomorphous mixture with cementite and that in steels containing 15 to about 24 per cent a double carbide $2\text{Fe}_3\text{C} \cdot 3\text{Cr}_3\text{C}$ exists. In respect to this latter conclusion, however, their experimental methods have been questioned and severely criticised.

The self-hardening property of certain chromium steels—as evidenced by the lowering of the Ar_1 transformation with increase in initial temperature—has also long been recognized. Osmond¹ noticed this effect and also reported the tendency of a high percentage of chromium to raise Ar_1 . Carpenter, however, who likewise observed this latter effect, concluded that chromium cannot be regarded as an element which imparts a self-hardening property to steels, because by raising the temperature of occurrence of Ar_1 it hastens the carbide transformation. On the other hand, Edwards and Kikawa⁷ in studying high-speed tool steels more recently demonstrated that within certain limits of composition chromium has an even greater self-hardening effect than tungsten, and further that the cooling rate plays an important part in producing this property. Using steel containing 0.63 per cent carbon and 6.1 per cent chromium, the critical cooling velocity which produces self-hardening was determined. Its variation with initial temperature was observed, being lower as this temperature is higher. These authors also proposed a

theory concerning the dissociation of the carbide, considered to be Cr_3C_2 . According to their view, the carbide first goes into solution as $(\text{Cr}_3\text{C}_2)_2$ at the Ac_1 point and then gradually dissociates into Cr_3C_2 as the temperature

FIG. 1. THERMAL EXPANSION AND CONTRACTION CURVES OF SOME CHROMIUM STEELS

is raised, the carbide point being more readily lowered by this increase of the number of molecules in solution.

A Japanese paper comparing previous investigations and based on a study of the constitution of chromium steels⁸ containing less than 4 per cent carbon and 0.5 to about 90 per cent chromium was published in April, 1918, by Murakami. The effects of carbon and chromium and various thermal treatments on the A_1 transformation were studied by magnetic analysis, using a magnetometer and torsion balance described briefly in

FIG. 2. MAGNETIZATION-TEMPERATURE CURVES OF SOME CHROMIUM STEELS

CHEMICAL & METALLURGICAL ENGINEERING, vol. 24, p. 573, March 30, 1921. The latter apparatus was used for alloys worked with difficulty or not at all. Thermal-expansion measurements, as illustrated in Fig. 1, were used to study more closely effects of such variables on the A_1, A_2, A_3 transformations, while these tests were supplemented by and correlated with thermal analysis and microscopic examination. Typical magnetization-temperature curves are shown in Fig. 2.

The results of this investigation may be summarized as follows:

MAGNETIC ANALYSIS

1. Magnetic analysis shows that in steels containing relatively high carbon and low chromium the A_1 transformation occurs at about 700 deg. C. Increase in chromium content raises its position, a result which agrees with the work reported by earlier investigators. Similarly in low-chromium steels the magnetic transformation of cementite A_0 and that of the double carbide occurring at 150 deg. C. are found, the former disappearing before the latter as the proportion of chromium increases.

2. Certain chromium steels containing a relatively high proportion of chromium to carbon are self-hardening. The amount of lowering of the transformations increases with maximum temperature, increase of carbon or of chromium, the other element remaining constant. In steels of high chromium and low carbon the A_2 transformation is the only one found, decreasing as chromium increases.

3. The rate of cooling has a marked effect on the transformations. In steels for which the lowering does not take place by normal cooling it may be obtained by faster rates, and the transformation which is lowered by normal cooling is further suppressed by rapid cooling. Sufficiently slow cooling, however, throughout a range about 700 deg. C. will allow it to take place completely.

CONSTITUTION

After annealing at about 900 deg. C., and slowly cooling through the range about 700 deg. C., the iron:

carbon:chromium alloys may be divided into five classes having characteristics as noted. Parentheses indicate constituents present in a free state.

I. Alloys having three transformations at about 700, 210 and 150 deg. C. consist of $(Fe) + (Fe_3C)$ and (α) double carbide.

II. Alloys having two transformations at about 700 and 150 deg. C. consist of $(Fe) + (\alpha)$ and (β) double carbides.

III. Alloys having a single transformation at about 700 deg. C. consist of $(Fe) + (\beta)$ and (γ) double carbides.

IV. Alloys having the lowered A_1 transformation. Present in both regions IV and V of Fig. 3, region IV representing alloys consisting of $(Fe) + (\gamma + Cr_4C)$.

V. Alloys having only the A_2 transformation. Consist of $(Fe + Cr) + (Cr_4C + Cr)$. These steels show lowering on normal slow cooling provided the proportion of chromium to carbon is relatively low. They are martensitic. Very slow cooling through the range about 700 deg. C., however, sets the dissolved carbide free.

Murakami points out the fact that the only two regions where lowering occurs on normal cooling (IV and V) are those containing the carbide Cr_4C and concludes therefore that the lowering is related to this constituent and further proposes the following hypothesis: When alloys containing Cr_4C are heated to above the A_1 transformation the carbide changes thus:

The higher the temperature the further the reaction proceeds from left to right. During cooling Cr_3C_2 and chromium only slowly associate and by the retarding action of the latter the carbide change is lowered even in normal cooling.

Lowering of the transformations also occurs on rapid cooling from 1,200 deg. C. in alloys of region III, Fig.

FIG. 3. CONSTITUTIONAL AND STRUCTURAL DIAGRAM FOR IRON: CARBON: CHROMIUM ALLOYS

3, which is similarly explained by previous dissociation of the double carbide, producing Cr_4C . The formulæ proposed for the α , β , and γ double carbides and dissociation of the last two are given below:

α double carbide $(Fe_3C)_{18}Cr_4C$ (6.01 per cent Cr, 87.40 per cent Fe, 6.59 per cent C).

β double carbide $(Fe_3C)_9Cr_4C$ (11.30 per cent Cr, 82.18 per cent Fe, 6.52 per cent C).

Dissociation $2(Fe_3C)_9Cr_4C = (Fe_3C)_{18}Cr_4C + Cr_4C$.

γ double carbide $\text{Fe}_3\text{C} \cdot \text{Cr}_7\text{C}_3$ (52 per cent Cr, 42 per cent Fe, 6 per cent C).

Dissociation $9\text{Fe}_3\text{C} \cdot \text{Cr}_7\text{C}_3 = (\text{Fe}_3\text{C})_9 \cdot \text{Cr}_7\text{C}_3 + 8\text{Cr}_7\text{C}_3$.

On normal cooling these products of dissociation recombine, but in rapid cooling the components have not sufficient time to associate and lowering is produced.

Thus the self-hardening of a chromium steel is related to the lowering or complete suppression of the Ar_1

transformation, the hardness being caused by the solid solution of Cr_7C_3 in iron which has already dissolved chromium. Steels having the normal transformation point show troostitic or pearlitic structures, while those having the lowered transformation are martensitic. Where this transformation is completely suppressed the steels are austenitic.

Fig. 3 shows the locations where normal structures of

the forgeable alloys may be expected. Steels showing ferrite and pearlite are represented by a dot, those having the carbide primarily separated from austenite and pearlite by a circle and those having the carbide separated from the melt as a eutectic constituent by a dot inside a circle. Typical micrographs are shown in Figs. 4 to 15, inclusive.

Except as otherwise specified, alcoholic solutions of picric or nitric acids were used for etching alloys low in chromium, and an aqueous solution of hydrochloric acid for high-chromium steels. The double carbides of chromium and iron, except the α carbide, are not colored by sodium picrate solution, either hot or cold. An etching reagent consisting of 10 g. of potassium ferricyanide and 10 g. of potassium hydroxide dissolved in 100 c.c. water colors the γ double carbide brown in ten to twenty seconds, and turns it blue to yellow on longer immersion. The β double carbide is hardly colored by this reagent at room temperature, but is readily colored brown to blue when the solution is boiling. The α double carbide and cementite are colored brown in the boiling solution, but the color is less intense than that obtained by use of sodium picrate. The carbide Cr_7C_3 is hardly attacked by either hot or cold solution while the solid solution of iron and chromium is colored brown to blue.

Figs. 4 and 5 show typical structure of region III_b of Fig. 3, containing a quantity of γ double carbide which is not colored by the cold ferricyanide solution, acids or boiling sodium picrate. Cementite and α double carbide are shown in Fig. 6, it being possible to color the globules by boiling sodium picrate but not by the cold ferricyanide reagent.

γ double carbide dissolving some Cr_7C_3 is shown in Fig. 7, while in Fig. 8 is shown a ground mass of the solid solution of iron and chromium and a chain of fine globules of a solid solution of Cr_7C_3 in chromium. The coloration obtained in cold ferricyanide is shown in Fig. 9. This latter alloy belongs in region V_b of Fig. 3.

Figures 10, 11 and 12 show the effect of maximum temperature on the structure of the steel represented in normal condition in Fig. 7. White patches in Fig. 14 are martensite; dark are troostite. With increase in maximum temperature the patches of martensite become larger, as shown in Fig. 11, and in Fig. 12 the structure becomes entirely martensitic.

Figures 13, 14 and 15 show the effect of rate of cooling on the structure of a steel containing 1.09 per cent carbon and 9.33 per cent chromium. Slow cooling from 900 deg. C. results in pearlite (Fig. 13), while rapid cooling gives martensite, as shown in Fig. 14. On slow cooling from 1,200 deg. C. this steel shows martensite and troostite, while on rapid cooling from the same temperature austenite is retained (Fig. 15).

Hydro-Electric Development in Italy

Hydro-electric development in Italy has made rapid progress during the last few years. It is estimated that whereas in 1915 Italy's electric power resources amounted to 2,500,000,000 kw.-hr. per annum, this figure had been increased to 3,700,000,000 before the end of the war, and now approximates 4,000,000,000. Whereas in 1915 the capital of Italian electric companies was less than 600,000,000 lire, it now reaches about 1,500,000,000 lire. During the five years from 1915 to 1920 there were completed new hydro-electric plants yielding 265,000 hp., and plants now under construction will yield 400,000 hp. additional.

Synopsis of Recent Chemical & Metallurgical Literature

Present Status of the Synthesis of Ammonia by the Hyper-Pressure Method.—At the Feb. 21, 1921, meeting of the French Academy of Sciences, Georges Claude presented a note on the present status of the synthesis of ammonia by the hyper-pressure method. The first practical demonstration of the process before a number of members of the Academy took place Jan. 9, 1920, when the mixture $\text{N}_2 + 3\text{H}_2$ was first compressed to 100 atm. by an ordinary compressor of 60 cu.m. per hour capacity and then compressed by two hyper-compressors in series to 300 and 1,000 atm. The hyper-compressed mixture after it had been purified was passed through a catalyzer tube giving from 6 to 7 liters of liquid ammonia per hour. All the apparatus had to be placed in wells and the manipulations were difficult.

The second demonstration took place Nov. 20, 1920. At this time there were four catalyzing tubes instead of one. The tubes were arranged two in parallel and the other two in series and sufficient for the combination of 80 per cent of the gases treated. The tubes were placed in separate compartments located in a building on the ground. The same hyper-compressors were used as during the first demonstration, but were operated to produce 150 cu.m. per hour instead of 60. All the installation proved to be perfectly gas tight, as there was no trace of ammonia odor in the building. The production was 60 to 70 liters of liquid ammonia per hour—i.e., about 1.25 tons per day. This installation is still running for experimental purposes only. The hydrogen used is produced by an electrolytic cell and this makes its cost very high. Extensive research work is now going on to obtain cheaper hydrogen.

At the present time a great step in the process has already been realized—namely, the production by a single hyper-compressor of the two stages 100 to 300 atm. and 300 to 900 atm., which is the final pressure used. This hyper-compressor has been made by M. Le Rouge and compresses 700 cu.m. of the mixture per hour, a quantity sufficient to give 5 tons of anhydrous ammonia per day, equivalent to 25 tons of ammonium sulphate per day. The energy consumed for the compression of 710 cu.m. from 1 to 100 atm. was 187 hp. and for the compression from 100 to 900 atm. 122 hp.—i.e., about $\frac{1}{2}$ hp.-hr. is required to compress 1 cu.m. of the mixture to 900 atm. The tightness of the installation is such that under the hardest conditions of starting and stopping of the operations the loss of gas mixture was less than 0.5 per cent. One of the four catalyzing tubes of a capacity of 5 tons NH_3 per day was tested at the same time and found to work successfully.

Since former tests showed that it is easy to have all four tubes working simultaneously, the application of the process to large industrial units seems certain to prove successful, provided an adequate cheap source of hydrogen can be found.

Use of Belting in Fertilizer Plants.—The severe service to which belts are subjected in fertilizer factories makes their selection and care a matter of more importance than in most manufacturing establishments. Acid fumes and gritty dust are both found in varying quantities in every fertilizer plant, and both are enemies of belt efficiency. The introduction of electric motors in a number of the larger plants has reduced the amount of belting required, but there is no indication that any plant will ever be able to dispense altogether with belts.

Results of a study of the use of belting in this industry have been published in *American Fertilizer*, March 12, 1921, p. 57. Replies to a questionnaire were received from manufacturers having an annual output of a little over 3,000,000 tons, somewhat less than one-half of the total production.

Power transmission belting. An analysis of the data received indicates that the fertilizer industry in the United

States uses approximately 765,000 linear ft. of power belting, of which 85 per cent is rubber, $9\frac{1}{2}$ per cent leather, and $5\frac{1}{2}$ per cent fabric. The favor with which rubber belting is held in fertilizer factories is due primarily to its acid-resisting qualities. The fumes from the acidulating room and the acid reaction from the acid phosphate dust both affect largely the life of the belts. As long as the rubber coating on a belt completely protects the enclosed fabric the belt stands up well against acid vapors.

The first cost of a rubber belt is less, which is an additional argument in its favor. This was especially true when the war-time demand for leather reduced the supply available for belts. As a general rule leather belting is used on heavy drives which can be separated from the unfavorable factory conditions. This is often the case with the belt transmitting from the primary source of power. There is some leather belting in use which has been impregnated with an acid-resisting substance.

Dust is second only to fumes as a source of belt trouble in fertilizer factories. It increases the wear on the belt, and thus shortens the time, in the case of rubber belting, when the protective covering is worn through and the underlying fabric exposed. As soon as this occurs the deterioration of the belt is rapid. Dust also increases the slipping, which is an inherent weakness in rubber belting. This excessive slipping must be counteracted by running the belt tighter or by using a belt dressing. Both of these remedies are costly in the end. One company estimates that fumes and dust in its factory reduce the life of its belting by one-half.

Where care is taken to keep down dust, the increase in the life of the belt is noticeable. Some companies report that they have obtained nine and ten years of continuous service from favorably located rubber belts. As a general rule the unfavorable conditions in fertilizer factories more than counterbalance the natural superiority of leather belting for the transmission of power. Experience has demonstrated that rubber is better adapted for most of the work.

Conveyor belts. The conveyor belts in fertilizer factories vary in width from 12 to 30 in. From the figures received it is estimated that the industry uses about 28,000 linear ft. of conveyor belting, 89.9 per cent of which is rubber, and 10.1 per cent fabric. About 40 per cent of the manufacturers use conveyor belts.

The same conditions which affect the power belting cause deterioration in conveyor belting. A certain density of surface is necessary in conveyor belts to prevent the gritty material from working into the body of the belt.

Where the design of the building and the location of the machinery permits the use of bucket elevators and other devices for conveying materials, these are preferred to belt conveyors by a number of the manufacturers.

Test Code for Evaporating Apparatus.—In 1918 the Power Test Committee of the American Society of Mechanical Engineers was reorganized to revise and enlarge the power test codes of the society published in 1915. The committee is a large one, under the chairmanship of Fred R. Low, and under its direction are nineteen individual committees of specialists which are drafting codes for the different classes of apparatus comprised in power plant equipment. The third of these codes, the test code for evaporating apparatus, was published in *Mechanical Engineering*, vol. 43, p. 184, March, 1921. This code is intended primarily for apparatus heated by steam, such as vacuum pans or single- and multiple-effect evaporators.

Trade Notes on Bauxite.—In order to encourage the development of mineral resources, the Geological Survey of India has prepared a series of papers on the more important minerals. One dealing with bauxite, by J. Coggin Brown, has been published in the *Journal of Indian Industries & Labour*, vol. 1, part 1, p. 54, February, 1921. After discussing distribution of Indian deposits, uses, grades, specifications, other sources of supply and statistics, the question of the best method of developing the deposits is taken up. Since the present consumption of aluminum in India is comparatively small, manufacture of the metal on an economical scale would involve building up an export business. An alternative would be the manufacture of pure alumina locally for export to aluminum works or for the local manufacture of aluminum salts.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Carbon Bisulphide.—Through the use of a hot blast, a low blast furnace is operated as a slagging gas producer, anthracite, coke or charcoal being used as fuel. At the bosh, or just above the zone of highest temperature, sulphur vapors are introduced. Carbon bisulphide is formed by contact with the heated carbon, any SO_2 present in the vapors being reduced to CS_2 at the same time. It is even possible to use smelter gases and roaster gases instead of sulphur. The gases and vapors leaving the furnace are cooled in a condenser. This removes most of the moisture coming from the fuel, any sulphur vapor and a little CS_2 , the amount of the last depending upon the ratio of its vapors to the gas present. Carbon bisulphide is separated from the cooled mixture of gases and vapors by scrubbing with chilled oil. (1,369,825; KARL P. McELROY, of Washington; March 1, 1921.)

Electric System for Electric Furnaces.—HARRY A. GREAVES and HARRY ETHELLES, of Sheffield, England, have devised a system for the practical application of three-phase alternating current to an electric furnace having three (or a multiple of three) upper electrodes and a conductive hearth which is an electrical resistor in one unit. Each of the electrodes is connected to one terminal of the secondary windings of three transformers. The primary windings of the transformers are connected in delta and the secondaries in what is sometimes called an inverted star. The other terminals of the secondary windings and the lead from the hearth of the furnace are connected to a common point. Assuming the transformers to be of identical transforming ratios and the electrodes to be in equal adjustment, equal currents will pass through the secondaries, when the meshed primaries are excited by three-phase currents.

The common resultant current of the three electrodes will pass through the bath of liquid metal and through the resistance hearth of the furnace to the common point. This resultant current will be equal to twice the current passing through any one electrode and consequently any one transformer secondary winding. This arrangement has the additional advantage of making the arcs of a three-electrode furnace on a three-phase system entirely independent of each other, consequently making automatic regulation much more efficient. This also prevents fluctuations on one electrode circuit varying the current in the other electrode circuits. The permanent resistance of the furnace hearth also tends to damp short circuit currents passing through the electrodes, and consequently steadies the load fluctuations of the furnace as a whole. A better power factor is thus more easily maintained, as it is not necessary to introduce so much reactance as in furnaces in which the resistive hearth is not a feature. (1,370,016; March 1, 1921.)

Method of Making Wrought Iron.—Slag distribution in the usual puddle ball or bloom is coarse and the refining incomplete. This necessitates rolling the balls or blooms into bars which are then sheared, piled and re-rolled after heating to welding temperature. According to JAMES ASTON, of Pittsburgh, Pa., these operations may be eliminated by introducing slag into the product of a steel-making process in such a way that uniform slag distribution is obtained. In the preferred method, the molten substantially slagless product of a steel-making process is granulated while dropping through the air and is received in a receptacle containing a bath of molten slag of the proper consistency and temperature, so that a ball of mixed slag and metal will be formed below the surface of the slag in the receptacle. (1,370,507 and 1,370,622; assigned to A. M. Byers Co.; March 8, 1921.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Saccharine.—Saccharine is prepared by oxidizing *o*-toluene sulphamide with chromic acid mixed with sulphuric acid of more than 35 per cent strength. The chromic acid may be formed in situ by the use of a chromic acid salt. After cooling and diluting the reaction mixture, the product is filtered off and the saccharine separated from unchanged starting material by any known method. (Br. Pat. 153,520; SOC. CHIMIQUE DES USINES DU RHÔNE, Paris. Jan. 19, 1921.)

Acetic Acid.—In the manufacture of acetic acid by the oxidation of liquid acetaldehyde at 10 to 20 deg. C., the catalyst employed is the residue which remains after igniting the carbon from animal charcoal, with or without the addition of sodium acetate. As the residue mainly consists of calcium and magnesium phosphates, it may be replaced by a mixture of these compounds, with or without small quantities of lime, silicon dioxide and fluorides. (Br. Pat. 154,680, H. DREYFUS, London. Feb. 2, 1921.)

Treating Sulphide Ores of Lead and Zinc.—Sulphide ores of lead and zinc are treated with sulphuric acid containing free sulphur trioxide or with sulphur trioxide in the gaseous form to convert the lead, etc., into sulphates while the zinc remains in the form of sulphide. The lead sulphate is separated from the zinc sulphide, for instance, by flotation. Silver sulphate may be separated from lead sulphate by treatment with water. Cadmium and bismuth if present are converted into sulphates which are readily separated from lead sulphate. (Br. Pat. 154,718, P. A. MACKAY, London. Feb. 2, 1921.)

Potassium Sulphate.—The production of potassium sulphate and hydrochloric acid from a pulverulent mixture of potassium chloride and aqueous sulphuric acid is effected in a single direct-flame furnace having a long flame, and which may be divided into three compartments if necessary, the arrangement being such as to provide for desiccation at a low temperature, say 120 to 300 deg. C., heating at 300 deg. C. and finally heating at 700 to 800 deg. C. Alternatively a compound furnace may be employed allowing the same stages of heating, in which one or more of the stages is effected by indirect heat as in a muffle. In another modification the process is effected in a single furnace so as to obtain first a desiccation at 120 to 300 deg. C. and in the rest of the furnace a temperature increasing from 300 to 800 deg. C., care being taken that the mass moves through the desiccating section slowly enough to remain solid and porous. The sulphuric acid may be of strength exceeding 70 to 72 per cent SO_3 . (Br. Pat. 154,111; FABRIQUES DE PRODUITS CHIMIQUES DE THANN ET DE MULHOUSE THANN, France. Jan. 26, 1921.)

Casein Compounds.—Metallic pyrophosphate casein compounds, which are of use in therapeutics, are prepared by dissolving casein in alkali pyrophosphate solution and adding a metallic salt, such as calcium chloride or ferric chloride. (Br. Pat. 154,112; F. HOFFMANN-LA ROCHE & Co., Basel, Switzerland. Jan. 26, 1921.)

Cellulose Acetate.—In the manufacture of solutions, celluloid-like masses, films, dopes, artificial silk and other compositions, and preparations and articles having a basis of cellulose acetate, the following high boiling-point or plastic-inducing agents are employed: Benzene monomethylsulphonamide, benzene methylethylsulphonamide, mixtures of *o*- and *p*-toluene dimethyl- or diethyl- or methylethylsulphonamides, *o*-toluene dimethyl- or diethylsulphonamides, or mixtures of isomeric xylene dimethyl- or diethyl- or methylethylsulphonamides; or mixtures of these dialkylsulphonamides and the monoalkylsulphonamides referred to above or in specifications 132,283 and 133,353 may be used. In conjunction with these high boiling-point solvents there may be used any other suitable low boiling-point solvents, agents such as triphenyl or tricresylphosphate, acid neutralizing aliphatic derivatives of urea such as mono-, di-, or tri-methyl, or tri-ethyl-urea, coloring matters and filling materials. The benzene methylsulphonamide may be prepared from com-

mercial benzene, for example, distilling between 79 and 88 deg. C., the sulphochloride being first prepared and then treated either with ammonia and afterwards with suitable alkylating-agents, or directly with suitable amines; the mixtures of *o*- and *p*-dialkylsulphonamides, from commercial toluene distilling between 95 and 132 deg. C., the *o*-toluene dialkylsulphonamides, from pure toluene distilling between 110 and 111 deg. C.; the mixtures of isomeric xylene dialkylsulphonamides, from commercial xylene distilling between 135 and 146 deg. C. (Br. Pat. 154,334; H. DREYFUS, London, Jan. 26, 1921.)

Electrolytic Detinning Process.—Tin is dissolved from tinned scrap, etc., by a strong solution of tin and iron chlorides, preferably containing a small proportion of hydrochloric acid. A suitable solution is made by treating a 25 per cent solution of ferric chloride with 1 per cent of hydrochloric acid and with metallic tin until it contains 6.5 per cent of stannous chloride and 1.5 per cent of stannic chloride. This solution, after use for dissolving tin from scrap, is electrolyzed to deposit a small amount of tin, equal to that dissolved from the scrap, for instance 0.2 per cent of the solution, the current density and rate of flow and speed of the cathode being regulated to attain this end, and to deposit non-adherent tin, which is scraped off the rotary cathode. The scrap may be placed in two enameled baskets *a*, Fig. 1, hung from the ends of a beam *b* centrally supported by lifting tackle from a carriage *c*. Three pairs of tanks *f*, *g*, *h* are successively used for the treatment, the liquid being admitted from a heater *w* by separate cocks *y* and afterward pumped to a storage tank *u*, whence it is led through a cock *t* to the electrolytic cell *k* and back to the heater. After detinning, the scrap is washed in tanks *i* and coppered or treated with lime water in tanks *j*. The electrolytic cell may comprise an anode *l*, Fig. 2, of trough form and preferably of graphite impregnated with paraffine wax. Copper conductors 2 are embedded in the anode. Electrolyte flows over both edges of

the anode into the trough and through holes in the bottom to a well *o* and outlet pipe *q*. The deposited tin is removed from the cylindrical rotating cathode *r* by a scraper 3. The speed of the cathode may be 10 in. per minute, the current density 450 amp. per sq.ft., and the rate of flow 10 gal. per hour through a channel $\frac{1}{2}$ in. x 6 in. between the electrodes. (Br. Pat. 154,242; M. A. ADAM, J. STEVENSON and A. T. MABBITT, all of London. Jan. 26, 1921.)

Acetic Acid.—In the manufacture of acetic acid by the oxidation of liquid acetaldehyde, the catalyst employed is kaolin, with or without the addition of sodium acetate. The temperature is preferably maintained at 10 to 20 deg. C. If, instead of oxygen, gas containing oxygen be employed for the oxidation, it is introduced at a pressure up to 7 atmospheres. (Br. Pat. 154,304; BRITISH CELLULOSE & CHEMICAL MFG. CO., London; M. SOLLER, Ruddington, Nottinghamshire, and J. HOLTZ, Spondon, Derbyshire. Jan. 26, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Final Decree in the Salt Lake Smoke Suits

On March 21, 1921, Federal Judge T. O. Johnson signed various orders setting aside all previous judgments and stipulations regarding the operation of the Murray smelter of the American Smelting & Refining Co. and the Midvale smelter of the United States Smelting, Refining & Mining Co., formerly ordered with a view of avoiding smoke damage to the surrounding country. Based upon the report of Commissioner Robert E. Swain—reviewed at length in *CHEMICAL & METALLURGICAL ENGINEERING* March 16, 1921, page 463—the court finds that both of these smelting plants can be operated at their present locations without injury to their neighbors, and they are permitted to operate subject to the following conditions:

"1. That all necessary measures shall be taken to maintain all furnaces, flues and other portions of the plant in such good operating condition as to prevent excessive leakage of noxious gaseous or solid emanations.

"2. That all gases and accompanying solid emanations or dusts from roasting or blast-furnace operations shall be subjected to bag filtration, or to electrical precipitation by the Cottrell process, or to any other process or processes of equal efficiency for the removal of suspended solids, sulphur trioxide or sulphuric acid, and that these installations or processes shall be maintained and operated at the highest practicable efficiency; provided, however, that if blast-furnace gases and their accompanying solid emanations or dusts are treated by the Cottrell process, they shall first be conditioned by the addition of sulphuric acid or other modifications in the present process, made to give it an operating efficiency equal to that which it shows in the treatment of the gases and other emanations and dusts from roasting furnaces.

"3. That all gases from roasting operations shall be discharged at a point not less than 450 ft. above the level of the ground, and that through heating apparatus installed at the base of the exit stack, or by other means, there shall be maintained during the growing season for vegetation in this district, during the time each day between sunrise and sunset when roasting operations are in progress, a difference in temperature between the stack gases at any point of measurement within the stack and the outside air amounting to at least 75 deg. C.; provided, however, that upon proper showing to the court, a commissioner may be appointed to receive any submitted evidence and make any necessary investigations, at the expense of the applicant, with a view to the formulation of any modification of the provisions as to temperature of gases hereinabove set out in this paragraph.

"4. The United States Smelting, Refining & Mining Co., one of the defendants, expressed its willingness to make such alterations and improvements in its smelter as to enable it to operate the same subject to the foregoing conditions; it is further ordered that it be permitted to continue to operate subject to the conditions and limitations specifically set forth in the interlocutory decree made on Jan. 21, 1921*, with the proviso that said defendant shall proceed with all due diligence to so alter its smelter as to permit it to operate the same subject to this decree."

National Research Council, Division of Chemistry

The annual meeting of the Division of Chemistry, National Research Council, will be held at Rochester at 12:30 Wednesday, April 27. The various committees will report upon activities of the past year. There will be a general discussion of plans and projects for the ensuing year.

*See "Smoke Litigation in Salt Lake Valley," *CHEM. & MET. ENG.*, vol. 22, p. 1145, June 23, 1920.

Hoover Resigns as President of Engineering Council

At the meeting of the executive board of American Engineering Council in Philadelphia, April 16, noted elsewhere in these columns, Herbert Hoover tendered his resignation as president of American Engineering Council. He did this because he considered that the activities of the council and of the Federated American Engineering Societies in national affairs would be likely to place him in an embarrassing position on account of his Cabinet post. He indicated that his interest in the work of the council and of the federation had in no degree diminished. In fact, he reiterated that he believed the formation of the Federated American Engineering Societies was the starting point of one of the most valuable voluntary services that could be rendered the nation.

His successor as president of the council was not elected at the meeting, but the selection was referred to the consideration of the council's committee on procedure.

Engineering Council's Executive Board Meets

The executive board of American Engineering Council held its regular bi-monthly meeting in Philadelphia on April 16 at which it was decided to hold an "Engineering Assembly" in Washington in January, 1922. The remaining time of the sessions was devoted to the consideration of reports of committees and the reference to these committees of various new matters brought to the consideration of the board.

The "Engineering Assembly" is to be a two-day session for the discussion of engineering problems. A committee was appointed to make arrangements for holding it.

The secretary reported the completion of the moving of the office of the council to Washington, the retention of A. C. Oliphant as assistant secretary, and the engagement of James T. Grady to handle publicity.

The Duluth Engineering Society, the Boston Society of Civil Engineers and the Milwaukee Engineering Society were admitted to membership. The next meeting was fixed for June 3, and, according to previous decision, will be held in St. Louis. W. W. Varney, who has been serving as acting treasurer, was elected treasurer.

The committee on public affairs reported that it deemed it inadvisable for the council to engage in activities with reference to the general reorganization of the government. It believes that the council will be stronger if it confine its efforts to presenting to Congress and the public the merits of the proposal to establish a Department of Public Works.

Investigation of Fertilizers Sold in Pennsylvania

The State Department of Agriculture, Harrisburg, Pa., has concluded an investigation of fertilizers sold in the state during the past year. A total of 1,312 samples was tested, showing a deficiency of 29.9 per cent in one or more of their guarantees for nitrogen, phosphoric acid and potash. The samples represented 676 different brands of fertilizers manufactured by a total of seventy-seven manufacturing companies. The largest proportion of deficiencies was found in the complete fertilizers supplying potash, nitrogen and available phosphoric acid.

To Concentrate C.W.S. Work at Edgewood

Training activities and the proving of shells and other ordnance have been conducted on a considerable scale at Lakehurst. In the future these activities will be transferred to Edgewood.

The proving grounds at Edgewood are somewhat limited, but will serve most of the purposes of Chemical Warfare Service tests.

Tentative Program of the Rochester Meeting of the American Chemical Society

The following program was announced by Secretary Parsons on Friday, April 15:

Monday, April 25

- 4:00 p.m.—Council Meeting, Rochester Club.
6:30 p.m.—Dinner to the Council at the Rochester Club.

Tuesday, April 26

- 9:30 a.m.—General Meeting at Chamber of Commerce, 67 St. Paul St.
Addresses of Welcome, Hiram Edgerton, Mayor; E. G. Miner, Chamber of Commerce.
Response, President Edgar F. Smith.
2:00 p.m.—Some Problems of National Defense, Hon. James W. Wadsworth.
The American Chemical Industry, Hon. Nicholas Longworth.
Ammono Carbonic Acids, E. C. Franklin.
Measurement of Color, C. E. K. Mees.
Blue Eyes and Blue Feathers, W. D. Bancroft.
Surface Films as Plastic Solids, R. E. Wilson.
Stability and Structure of Molecules, Irving Langmuir.
Ionization of Electrolytes, G. N. Lewis.
6:30 p.m.—College, Fraternity and Group Dinners.

Wednesday, April 27

- 9:00 a.m.—Division Meetings, Mechanics Institute, 55 South Plymouth Ave.
8:00 p.m.—Chemistry in the United States, Charles F. Chandler.

DIVISION OF PHYSICAL AND INORGANIC CHEMISTRY

Symposium on Contact Catalysis, 9 a.m.

- Platinum Black and Carbon Monoxide, F. H. Pollard.
Esterification of Silica Gel, C. H. Milligan and E. Emmet Reid.
Adsorption by Oxide Catalysts and the Mechanism of Oxidation Processes, A. F. Benton.
Dissociation of Some Mixed Oxides, J. C. Frazer.
Adsorption by Metallic Catalysis, R. M. Burns and H. S. Taylor.
The Action of Nickel on Diethyl Ether: A Study in Contact Catalysis. Preliminary Report, F. L. Simons.
R.P.M.'s as a Catalyst, C. H. Milligan and E. Emmet Reid.
Catalysis in the Reduction of Oxides and the Catalytic Combination of Hydrogen and Oxygen, R. N. Pease and H. S. Taylor.
A Case of Autoxidation: $\text{MnO}_2 \rightarrow \text{HMnO}_4$, J. C. Fraser.
Catalysis in the Interaction of Carbon With Steam and Carbon Dioxide, N. A. Neville and H. S. Taylor.
Oxidation and Reduction by Organic Compounds, C. H. Milligan and E. Emmet Reid.
The Action of Alumina, Titania and Thoria on Ethyl and Isopropyl Acetate, Homer Adkins and A. C. Krause.
Catalytic Electrolytic Oxidation of Sulphur Dioxide, C. G. Fink.
The Decomposition of Ethyl Acetate Induced by Catalytic Nickel, Homer Adkins and P. W. Simmonds.
The Catalytic Influence of Foreign Oxides on the Decomposition of Silver Oxide, Mercuric Oxide and Barium Peroxide, James Kendall and Francis J. Fuche.

Papers at 2:30 P.M.

- A New Clock Reaction, G. S. Forbes, H. W. Estill and O. J. Walker.
The Volumetric Oxidation of Sulphide to Sulphate, H. H. Willard and W. E. Cake.
Research for the Undergraduate, Edward Ellery.
The Apparent Irreversibility of the Calomel Electrode, A. W. Laubengayer.
The Theory of Hydrogen Over-Voltage, D. A. MacInnes and W. R. Hainsworth.
The Hydrogen Electrode Under High Pressures, D. A. MacInnes and W. R. Hainsworth.
Potassium Ammonoaluminate and Ammonomanganite, Francis W. Bergstrom.
A Quantitative Study of Adsorption in Solution and at Interfaces of Sugars, Dextrine, Starch, Gum Arabic and Egg Albumen and the Mechanism of Their Action as Emulsifying Agents, G. L. Clark and W. W. Mann.
The Preparation, Properties and Molecular Volume Relationships of the Ammines and Hydrates of Cobalt Fluoride, Bromide, Nitrate, Carbon and Citrate, G. L. Clark and H. K. Buckner.

Emulsification With Soaps of Linoleic and Ricinoleic Acids, G. S. Clark and H. K. Buckner.

Notes on the Preparation of Pure Platinum, Edward Wichers.

Modified Method for the Determination of Iron and Vanadium After Reduction, E. F. Lundell.

The Free Energy of Dilution of Hydrobromic Acid; the Activities of Its Ions in Very Dilute and Concentrated Solutions, H. Miller Spencer and Albert G. Loomis.

Ultra-Violet Arc Spectrum of Yttrium, L. F. Yutema and B. S. Hopkins.

On the Viscosity of Gelatin Sols, R. H. Bogue.

The Structure of the Molecule of Water, Irving Langmuir.

The Purification of Helium by Means of Charcoal, L. Finkelstein.

The Importance of Diffusion in Organic Electrochemistry, Robert E. Wilson.

Observations on the Drying and Swelling of Gelatine Gels, S. E. Sheppard and F. A. Elliott.

Note on the Influence of Silver Salts in Catalyzing the Decomposition of Ammonium Persulphate Solutions, S. E. Sheppard and A. Ballard.

Further Developments of the Hydrogen Electrode, F. A. Elliott.

Note on Silver Soap Gels, Stafford Whitby.

Catalytic Effect in the Reaction Between Ketones and Halogens in Aqueous Solutions, F. O. Rice.

The Transference Numbers of Sulphuric Acid by the Concentration Cell Method, Alfred L. Ferguson.

The Influence of Gelatin on the Transference Number of Sulphuric Acid, Alfred L. Ferguson.

The Entropy of Monatomic Gases, Gilbert N. Lewis.

The Electrometric Titration of Uranium With Potassium Dichromate and Potassium Permanganate, D. F. Ewing and E. F. Eldridge.

The Heat of Coagulation of Ferric Oxide Hydrosol by Electrolytes, Frederick L. Brown and J. H. Mathews.

Some Quantitative Experiments on Coagulation of Colloids, Ray V. Murphy and J. H. Mathews.

The Alkalinity of Searles Lake Brine, Roger C. Wells.

The Vapor Density of Technical Phosgene, A. F. O. Germann and Vernon Jersey.

The Cryoscopy of Boron Trifluoride Solutions: V. Systems With Methyl Ether and With Methyl Chloride, A. F. O. Germann and Marion Cleaveland.

The Cryoscopy of Phosgene Solutions: I. System With Chlorine, A. F. O. Germann and Vernon Jersey.

Studies in Fluoride Equilibrium: I. Calcium Borofluoride, A. F. O. Germann and Gilberta Torrey.

Chromatic Emulsions, H. N. Holmes and D. H. Cameron.

Cellulose Nitrate as an Emulsifying Agent, Harry N. Holmes and Don Cameron.

A Theory of the Photographic Latent Image, Harris D. Hine.

The Interaction of Platinum Hydrochloric Acid and Hydrogen Peroxide, S. A. Braly and O. V. Schoefer.

Is There a Sharp Transition Point Between the Gel and Sol? Eugene C. Bingham.

The Validity of the Additive Fluidity Formula, Eugene C. Bingham and Delbert F. Brown.

The Emulsion Colloids as Plastic Substances, Eugene C. Bingham and William L. Hyden.

The Properties of Cutting Fluids, Eugene C. Bingham.

DIVISION OF INDUSTRIAL AND ENGINEERING CHEMISTRY

H. D. Batchelor, chairman; H. E. Howe, secretary.

On Wednesday morning the Division will attend the symposium on contact catalysis held by the Division of Physical and Inorganic Chemistry.

Symposium on Drying, 2 p.m. Charles O. Lavett, chairman
The Rate of Drying Solid Materials (Lantern), W. K. Lewis.

The Theory of Atmospheric Evaporation (Lantern), W. H. Carrier.

The Compartment Dryer (Lantern), W. H. Carrier and A. E. Stacey.

Direct Heat Rotary Drying Apparatus, R. G. Merz.

Tunnel Driers (Lantern), G. B. Ridley.

The Spray Process, R. S. Fleming.

Vacuum Drying (Lantern), Charles O. Lavett and D. J. Van Marle.

General Papers

Tests of Counter-Current Kelp Driers, G. C. Spencer and E. B. Smith.

The Preparation, Properties and Constitution of Liquid and Solid Water-Glasses, Louis Schneider.

Method for Treating Filter Cake Obtained in Refining Vegetable and Animal Oils, Charles Baskerville.

The Application of the Cottrell Precipitator to the Wood Distillation Process, L. F. Hawley and H. M. Pier.

Alcohol and Chemical Industries, J. M. Doran.

The Caustic Calcination of Dolomite and Its Use in Sorrel Cements, C. A. Bole and J. B. Shaw.

Valuation of Oil-Bearing Seeds by Free Fatty Acid of the Oil, Lehman Johnson.

The Detection of Carbon Monoxide (Lantern), C. R. Hoover.

Microscope Illumination With Reference to Brownian Movement and Combination Lighting (Lantern), A. Silverman.

The Relation of Structure to Free Alkali in Sodium Silicate Solutions (Lantern), William Stericker.

Compression Evaporation, A New Method of Concentrating Liquids, Developed in Europe Recently (Lantern), Gustav Carlsson.

Action of Lime on Greensand, R. Norris Shreve.

A Modification of the Acetate Method for Estimating Iron and Aluminum in Phosphates, F. P. Veitch and H. P. Holman.

The Water Resistance of Treated Canvas During Continuous Exposure to Weather, F. P. Veitch and T. D. Jarrell.

The Detection and Estimation of Coal Tar Oils in Turpentine, V. E. Grotlisch and W. C. Smith.

THE CELLULOSE SECTION

9 a.m.

Effect of Adding Various Chemicals to Wood, Previous to Distillation, L. F. Hawley.

The Removal of Free Acid From Nitrated Cellulose, With Special Reference to the Use of Saline Leaches, S. E. Sheppard.

Motor Fuel From Vegetation (Lantern), T. A. Boyd.

Possibilities of the Moist Tropics to Furnish Materials for Cellulose and Carbohydrates (Lantern), H. N. Whitford.

The Possibilities of a Future Fuel Supply From Our Forests, R. C. Hawley.

The Role of the Chemist in Relation to Our Future Supply of Liquid Fuel, Harold Hibbert.

The four last-mentioned papers will be discussed together under the general subject, "Our Future Supplies of Liquid Fuel." It is expected that representatives of the Standard Oil Co., U. S. Industrial Alcohol Co., Forest Products Laboratory and others will take part.

The Microstructure of Wood (Lantern), Allen Abrams.

Significance of the So-Called Lignin Tests, E. C. Crocker.

Some Commercial Possibilities of Corn Cob Cellulose, F. B. LaForge.

Nitrocellulose and Its Solutions as Applied to the Manufacture of Artificial Leather, W. K. Tucker.

Influence of Mixed Acids on the Character of Nitrocellulose (Lantern), W. J. Waite.

A Proposal for a Standard Cellulose to Be Available for Research, B. Johnsen.

A Discussion of Some Beater Furnish Reactions From the Standpoint of Colloidal Chemistry, Jessie E. Minor.

The Solubility of Cellulose Acetate in Chlorinated Hydrocarbons, Gustavus J. Esselen, Jr.

The Action of Dry Hydrobromic Acid on Cellulose and Related Derivatives, Harold Hibbert and Harold S. Hill.

The Oxidation of Cellulose, W. S. Holzberger.

European Practice in Cellulose Acetate and Dopes During the War, Philip Drinker.

The Influence of Temperature on Hemi-Cellulose Production, W. E. Tottingham.

The Chemical Changes Involved During Infection and Decay of Wood and Wood Pulp, Mark W. Bray and Joseph A. Staidl.

The Chemical Constitution of Soda and Sulphate Pulp From Coniferous Woods and Their Bleaching Qualities, Sidney D. Wells.

SECTION OF PETROLEUM CHEMISTRY

T. G. Delbridge, chairman; W. A. Gruse, secretary.

9 a.m., Room 112

Organization.

Petroleum Hydrocarbons That Cannot Be Distilled, C. F. Mabery.

Petroleum: A Raw Material for Our Chemical Industries, Sidney Born.

Some Chemical Considerations of Petroleum Refining, B. T. Brooks.

Viscosity-Temperature Curves of Fractions of Typical American Crude Oils (Lantern), E. W. Dean and F. W. Lane.

Determination of Gasoline in Natural and Casinghead Gas, Charles Skeeel Palmer.

Dechlorination of Chlorohydrocarbons, W. F. Faragher and F. H. Garner.

Viscosities of Motor Oils at High Temperatures. (By title), L. B. Lockhart.

Oil Shale, R. F. Bacon.

Iodine Numbers of Unsaturated Hydrocarbons and Cracked Gasolines (Lantern), W. F. Faragher, F. H. Garner and W. A. Gruse.

A New Method of Color Measurement for Oils, Leon W. Parsons and Robert E. Wilson.

Total Heats and Condensation Points of Kerosene-Air Mixtures, Robert E. Wilson and D. P. Barnard.

Reclamation of Used Motor Oils (Lantern), W. F. Parish.

Catalytic Oxidation of Petroleum Oils, C. E. Waters.

Accurate Determination of Moisture in Transformer Oils, C. J. Rodman.

DIVISION OF RUBBER CHEMISTRY

W. W. Evans, chairman; Arnold H. Smith, secretary.

9 a.m., Room 109

The first day will be devoted entirely to a discussion of the Tentative Procedure for the Analysis of Rubber Goods.

Thursday

Reports from Executive Committee, Abstract Committee, Accelerator Committee and Physical Testing Committee.

Some Effects of PbO and SO₂ in Zinc Oxide on Compounded Rubber (Lantern), Harlan A. Depew.

Contribution to the Knowledge of the Resins of Hevea Rubber (Lantern), G. Stafford Whitby and J. Dolid.

The Solubility of Gases in Rubber as Affecting Their Permeability, C. S. Venable and Tyler Fuwa.

The Analysis of Rubber Goods Containing Antimony Sulphide, S. Collier and M. Levin.

Reactions of Accelerators During Vulcanization. III. Carbosulphydryl Accelerators and the Action of Zinc Oxide, C. W. Bedford and L. B. Sebrell.

The Influence of Piperidine-piperidyl-dithiocarbamate on Vulcanization (Lantern), G. Stafford Whitby and O. J. Walker.

A Rapid Bomb Method for the Determination of Sulphur in Rubber Compounds, W. W. Evans and Ruth E. Merling.

The Direct Determination of Sulphur of Vulcanization, S. Collier and M. Levin.

Volume Increase of Compounded Rubber Under Strain (Lantern). With comments on the work of H. F. Schippel, Henry Green.

General Round Table Discussion. Topics are: Factory Control of Vulcanization. Testing of Crude Rubber as Received at the Factory. Reactions Between Sulphur and Various Softeners, and others.

DIVISION OF DYE CHEMISTRY

A. B. Davis, chairman; R. Norris Shreve, secretary.

9 a.m.

Contribution to the Estimation of H-Acid, Henry R. Lee.

A New Process for Alizarine, Charles W. Schaffer.

Bleaching of Dyed Cotton Fabrics, J. Merritt Matthews.

The Immediate Needs of Chemistry in America, William J. Hale.

Contribution to the Chemistry of Malachite Green, J. R. Minevitch.

New Developments in American Dyes and Coal-Tar Chemicals in 1920, G. R. DeLong.

Dyes Derived From Beta-Oxynaphthoic Acid and From J Acid With Reference to the Chemical Foundation Patents, A. Willard Joyce.

Quantitative Determination of Phenanthrene, Arthur D. Williams.

Alkali Fusions. III. Fusion of Phenylglycine o-Carboxylic Acid With Potassium Hydroxide and With Sodium Hydroxide for the Production of Indigo, Max Phillips.

Vapor Pressure Determinations on Naphthalene, Anthracene, Phenanthrene and Anthraquinone Between Their Melting and Boiling Points, O. A. Nelson and C. E. Senseman.

Nomenclature of Dyestuff Intermediates, J. W. Kinsman.

Thursday, April 28

9 a.m.—Division Meetings.

7 p.m.—Good Fellowship Meeting, Bausch & Lomb Dining Hall.

Friday, April 29

Excursions, 10 a.m.

Bausch & Lomb Optical Co.

Pfaunder Co.

Gas Plants—Rochester Gas & Electric Corporation.

Municipal Garbage Disposal Plant.

Municipal Sewage Disposal Plant.

Bastian Bros.

Excursions at 2 p.m.

Eastman Kodak Co., Kodak Park Works.

(a) General Excursion.

(b) Synthetic Organic Chemical Department.

Taylor Instrument Companies.

(a) Laboratory Equipment.

(b) Industrial Apparatus.

(c) High Temperature Apparatus.

Vacuum Oil Co.

Bartholomay Co.—Baskerville Refining Process.

Further details concerning the nature of these excursions will be available at the time of registration.

Ladies' Entertainment

A ladies' entertainment is planned for Tuesday afternoon in the Ad Club rooms. The local ladies will give a tea and musical in honor of the visiting ladies. The Goodfellowship Meeting is one at which every lady guest is expected to be present. Among other things there will be dancing.

The Chemical Industry From a Tariff Viewpoint

Speaking before a recent meeting of the Chemical Society of Washington, C. R. De Long, chief chemist of the Tariff Commission, discussed some of the more important questions which arise in tariff consideration of chemical commodities.

INDIRECT COMPETITION

In addition to direct competition offered by imports of the same chemical it is often necessary to consider indirect competition by similar commodities which are of a competitive nature. One of the most striking examples of indirect competition is afforded by the vegetable oils. Practically any vegetable oil may be used in the manufacture of soap and also, if properly refined, in the manufacture of food products, such as butter and lard substitutes. Taking the case of cottonseed oil: No direct tariff problem is presented by cottonseed oil itself, since it is produced in large quantities and a considerable surplus is exported. However, the indirect competition offered by soya bean and peanut oils is an important factor in the tariff consideration of cottonseed oil. The competition which vegetable oils—in the form of oleomargarine and butter substitutes—offer to the dairy interests is another important consideration in the tariff problems of the vegetable oils.

COMPENSATORY DUTIES

The problem of compensatory duty, or the adjustment of duties on raw materials and finished products, offers varied tariff problems. These duties are based on the theory that any duty placed on a raw material should be compensated for by a corresponding increase in duty on the finished product. Take, for example, the case of barytes and lithopone. Here we have a case in which the raw material for the manufacture of lithopone was almost exclusively imported before the war. During the war the manufacturers of lithopone were forced to develop domestic supplies of barytes in order to have an adequate supply of raw material. The commission has made a detailed investigation of the cost of manufacturing lithopone and of mining barytes in order to ascertain the extent to which barytes enters into the total cost of lithopone.

Along this same line a study of the relation between the duties on oil seeds and oils show that under the present tariff law there is no definite policy or similar treatment of this important group of commodities. In some cases both the oil seeds and the oils are free of duty. In other cases the duties on the seeds and the oils are so adjusted that there is a differential in favor of importing and crushing the seeds in this country, and in still other cases there is a differential in duties which favors crushing the seeds in foreign countries and importing the oils. In order to have adequate information for considering compensating duties on vegetable oils the Tariff Commission has made a detailed study of the yields obtained in crushing the various oil seeds.

There is a somewhat controversial theory that tariff duties should be based on the difference of cost of production at home and abroad on the assumption that thus a competitive market is increased. In addition to this function

costs often serve as an aid in arriving at compensatory duties, which has been previously discussed. Unsettled conditions both in the United States and in foreign countries have made it decidedly questionable whether costs of production have much meaning at the present time. With changing industrial conditions—such as decreases in wages and cost of raw materials—it is also a matter of doubt as to whether or not the cost of production can be obtained with any fair degree of accuracy. The commission, however, has made several investigations as to cost of production in the domestic chemical industry. These include, principally, the cost of producing certain intermediates and dyes, barytes, barium chemicals, lithopone, the cost of refining sugar and the cost of production of ferro-alloys.

In many of the cost investigations the commission has found that the cost varied widely in the same industry and there was very little uniformity in cost-finding methods. In the industries developed as a result of war conditions this situation may be attributed to stress in output without regard to costs or to proper methods of determining costs. These conditions were found particularly in the dye industry and in the manufacture of barium chemicals. It is to be regretted that a large number of chemical firms do not keep adequate cost records and that many of them simply balance their books once a year. About all they really know is whether they made or lost money. It is safe to say that the chemical industries as compared with other industries have been somewhat backward in the exchange of cost ideas and the discussion of problems which are common to all manufacturers. It is to be hoped that if the commission's investigations have accomplished nothing else they have started manufacturers to thinking more about costs and exchanging ideas in regard to cost methods. There is true in the case of the dye industry, which has had a committee studying uniform costs and has issued a comprehensive report on this subject. In addition, many firms have established adequate cost-finding methods as a result of the Tariff Commission's investigations.

The Tariff Commission can be of service to domestic manufacturers in presenting their cases to Congress. Very few manufacturers are willing to disclose their individual costs in a public hearing before committees of Congress. The commission has, however, found domestic manufacturers always willing to submit their costs to the commission in confidence, so that the commission can tabulate and compare individual costs and thus arrive at an average cost or at a method of presenting individual costs which would not reveal confidential information of the individual manufacturer.

TARIFF CLASSIFICATION OF CHEMICALS

An attempt to classify chemical commodities for tariff purposes presents many technical and difficult problems. Classification may be by specific mention, that is, enumeration by name. In this connection it must be remembered that trade and commercial designations prevail over scientific nomenclature and that details such as punctuation may affect court interpretations. In the past, specific mention of chemical commodities was necessary in order to obtain import statistics and therefore the more chemical commodities which were mentioned by name the more detailed were the imports of chemicals shown.

Another method of classifying chemicals is by the law of similitude. This method is probably more unfamiliar to the ordinary layman than any other. If an article is not mentioned by name in the tariff law, the next question to be decided is whether or not it is like some other article which is mentioned. The law of similitude requires that an article must be like another article in one of four particulars—namely, material, quality, texture or use. This law is further restricted in that it can be only applied to dutiable goods—that is, a chemical commodity cannot be exempted from duty because it is similar to an article specifically mentioned on the free list.

If an article is not free or dutiable, either by specific mention or by similitude, it must be classed under some general provision. The tariff laws contain provisions known as "basket clauses" such as "all other aluminum compounds" and "all chemical and medicinal compounds, preparations,

mixtures and salts." If an article is not dutiable or free under some such provision as a last resort to obtain revenue, customs officials usually class it under paragraph 385 as an unenumerated, unmanufactured article, or as an unenumerated manufactured article. In many of these general provisions in the tariff act the classification depends upon use. Such classification is one of the most difficult to administer. For example, at the present time tanning extracts are free of duty while all dyeing extracts are dutiable, although in many cases these products overlap in use.

SPECIFIC VERSUS AD VALOREM DUTIES

The question as to what kind of duties should be levied on any given commodity—that is whether specific or ad valorem (based on value)—is a controversial one. However, it should be pointed out that in particular cases either a specific or an ad valorem rate has certain advantages. General ad valorem duties are objected to on the theory that it offers a chance for undervaluation on imports and at the present time they would be assessed on depreciated currency, as under the present law all ad valorem duties are assessed on the foreign market value. On the other hand, it is evident that in the case of goods varying widely in value an ad valorem duty would bear more evenly on the different articles or different grades of a chemical commodity than would a specific duty.

RECLASSIFICATION OF CHEMICALS

Some of the difficulties of classifying chemicals from a tariff standpoint have been cited and the question arises as to how the difficulties may be overcome. As a result of the commission's study in the chemical industries it has collected much information which would be of service in solving many of these difficulties of classification. At the present time, the chemical division of the commission is engaged in a reclassification of chemicals in Schedule A and those chemicals in the free list. An attempt is being made to eliminate conflicts in language which have caused frequent litigation in the past; to eliminate old and obsolete terms in chemical commodities, and to substitute chemicals which have become of commercial importance since the passage of the act of 1913. Even with the information and experience which has been gleaned in the past three or four years, it is hardly possible to write a tariff classification and description of chemical commodities which will entirely eliminate possible litigation. Certain changes in language can be made, however, which will reduce litigation to a minimum. Such a report on reclassification of chemicals has been nearly completed by the Tariff Commission and is to be presented to the Committee on Ways and Means as an aid in the present tariff revision.

A.C.S. Committee to Visit Edgewood

The American Chemical Society's committee which is co-operating in an advisory capacity with the Chemical Warfare Service will spend April 22 and 23 at Edgewood Arsenal. The object of the visit is to obtain first-hand impressions as to the progress of the work and to discuss current problems with the scientific staff at the arsenal. By making the visit at that time, the members of the committee will have the advantage of knowing the latest developments in all phases of the work, making them better able to consult with many other chemists in regard to it at the Rochester meeting.

Award of Willard Gibbs Medal to Mme. Curie

The Chicago Section of the American Chemical Society will hold a function of unusual interest this year in the presentation of the Willard Gibbs Medal to Mme. Marie Curie on June 14. Plans are under way for staging a brilliant affair under the leadership of the chairman, Dr. W. Lee Lewis. Large committees of reception composed of members of the section, representatives of foreign governments and city officials are being organized. Mme. Curie on this occasion will deliver an address of interest at once to scientists and laymen.

Argument on Minerals Separation Supplemental Bill

On April 2 the United States District Court at Wilmington, Del., heard arguments on the supplemental bill through which Minerals Separation, Ltd., seeks to have Minerals Separation North American Corporation made a party plaintiff in the Miami suit. The testimony had previously been taken and various documents placed in evidence.

The controversy concerns an agreement of July 8, 1913, between Minerals Separation, Ltd., and Minerals Separation North American Corporation and relates to whether this agreement did or did not constitute a sale of the patents of Minerals Separation, Ltd., or whether it was nothing more than a transfer to Minerals Separation North American Corporation of the equitable rights in those patents, leaving Minerals Separation, Ltd., the legal owner. The debatable points for the most part appear to be legal technicalities as to whether a certain transaction constituted an actual sale through which ownership of the patents passed from Minerals Separation, Ltd., to Minerals Separation North American Corporation at a time prior to the filing of the Miami infringement suit. If decided in the affirmative, the Miami suit would be dismissed. The controversy also centers in the question as to whether the failure of Minerals Separation North American Corporation to make the required disclaimer as to the claims of its patent which were declared invalid by the U. S. Supreme Court may not affect the rights of Minerals Separation, Ltd., to bring suit under the patent.

Weeks Considering Nitrate Division's Report

The Secretary of War is giving personal consideration to the question of continuing the Fixed Nitrogen Laboratory which the Department is conducting at American University, Washington, D. C. A full report on the needs of such a laboratory has been submitted by Major J. H. Burns, who is in charge of the Nitrate Division of the Ordnance Department. Secretary Weeks advised the Washington correspondent of CHEMICAL & METALLURGICAL ENGINEERING on April 13 that he had not reached a decision in the matter. He also stated that he had not made up his mind as to whether it is better to try to maintain the nitrate plants at Muscle Shoals in standby condition or whether there is a possibility of devising some means for their operation.

American Oil Chemists' Society to Meet in Chicago

The annual convention of the American Oil Chemists' Society will be held May 16 and 17 in Chicago, with headquarters at the Congress Hotel. Among the prominent chemists who will address the meeting is Dr. C. L. Alsberg, of the Bureau of Chemistry. The entertainment committee, with L. M. Tolman, chief chemist of Wilson & Co., as chairman, has planned numerous excursions, besides the usual banquet, which will occur on Tuesday evening.

As there are many chemists in and near Chicago interested in edible and technical oils and fats, the attendance promises to be larger than usual this year.

Thomas B. Caldwell of Wilmington, N. C., the secretary of the society, will be glad to furnish anyone interested with further details.

Protective Tariff Asked for South's Minerals

A formal request for a protective tariff on a number of mineral products produced in the South has been asked by representatives of these industries who appeared recently before the sub-committee on metals of the Ways and Means Committee. Schedules which will insure the development of the following minerals were asked: Asbestos, barytes, bauxite, clay, gypsum, graphite, marble, monazite, manganese, mica, potash, pyrites, quicksilver, sulphur, talc and zinc.

The Southern Tariff Association assisted in presenting the case. It was declared that nothing short of adequate duties would enable the development of the great mineral resources of the South, particularly the non-metallic minerals.

Book Reviews

THE DETERMINATION OF HYDROGEN IONS. By W. Mansfield Clark. 318 pp., illustrated. Baltimore: Williams & Wilkins Co., 1920. Price, \$5.

The most striking advance in analytical technique of the last five years has been in the exact determination of hydrogen ion concentrations, and, concomitantly, one of the most significant contributions of chemistry to the biological sciences and to a host of chemical applications has been the clear distinction between "available acidity" and "effective acidity," also called "total" and "actual" acidities, though Clark uses none of these terms. The determination of total, available or "titrable" acidity by titration has long been common practice, though with difficulty in colored, turbid or "buffer" media. The determination of how much of this acidity is present as actual hydrogen ions, and therefore effective, is recent, and the methods developed have been invaluable.

In this development Dr. W. Mansfield Clark has played a leading part, and this book embodies the experience of a master. It is thorough, both in theory and in laboratory suggestions, precise, and replete with references. The bibliography alone (64 pages) justifies the book. The theory presented is complete and rigorous; no pains are spared to discuss every possible difficulty in the methods; insidious errors are elucidated.

A list of chapter headings will prove this point: Some general relations among acids and bases; outline of the chief calorimetric procedure; theory of indicators; choice of indicators; standard buffer solutions for colorimetric comparisons; approximate determinations with indicators; outline of the electrometric method; theory of the hydrogen electrode; potential differences at liquid junctions; hydrogen and calomel electrodes and electrode vessels; the potentiometer and accessory equipment; hydrogen generators, wiring, shielding, temperature control, purification of mercury; the relation of hydrogen electrode to reduction potentials; sources of error in electrometric measurements of p_H ; standard solutions for checking hydrogen electrode measurements; standardization of p_H measurements; supplementary methods; applications; bibliography.

Addressed to research workers in the biological sciences, the book admirably fulfills its purpose and equips them for the justly feared task of determining p_H to the third decimal. It makes usable the excellent precise apparatus developed by American manufacturers. Its strength in this aspect is, however, rather an obstacle to chemists. Except in biological media the third decimal of the p_H value is not significant, and the corresponding measurement of voltage to the fourth decimal is wholly unnecessary. While dangers and pitfalls are faithfully pointed out, no safe path is recommended. Full discussions of the effect on the fourth decimal of the purification of calomel and the size of calomel grains, etc., which form the mass of the book—protein errors, salt errors, and a host of others—give the unfortunate impression that the determination of hydrogen ions is a tremendous task and one to be undertaken only by those whose funds and time and intellect are unlimited.

This is unfortunate both because p_H measurements to the first decimal are actually among the easiest of all chemical determinations either by calorimetric or by electrometric means, and because such determinations when thus simply made give valuable information in almost numberless cases. It is not improbable that the majority of industrial acidimetric titrations, which give total acidity, should be replaced by measurements of the actual or effective acidity. Yet the needs of the industrial chemists are not considered in this book. The reviewer therefore regrets that Dr. Clark did not add a few brief chapters on simplified theories, methods and applications, for which there is such a demand. The fact remains, however, that he has produced a book that for many years will be indispensable to research workers.

GERALD L. WENDT.

Personal

HUBB BELL has left the Pittsburgh Testing Laboratory and is now with the United States Testing Co., Inc., 313 Hudson St., New York City.

RALPH W. BOYD has resigned as chemist of the metallurgical research department of the Colorado School of Mines and is now associated with the Desert Shale Oil Corporation of Salt Lake City.

WALTER E. DALY, secretary and treasurer of the Pioneer Alloy Products Co., will leave for Rio de Janeiro and Buenos Aires the first part of May.

F. P. GEYER, chief geologist of the Maryland Refining Co., Ponca City, Okla., has been elected a director of the company, succeeding J. Dawson Callery, resigned.

Major ADELNO GIBSON, who has been on duty with the General Staff, has been ordered to report to the chief of the Chemical Warfare Service.

Dr. FREDERICK GOWLAND HOPKINS, professor of biochemistry at Cambridge University, England addressed the students of Johns Hopkins Medical School, Baltimore, Md., on April 12.

B. F. JONES has resigned as president of the Republic Rubber Co., Youngstown, Ohio.

Dr. R. E. ROSE, director of the technical laboratory of the dyestuffs department of E. I. du Pont de Nemours & Co., Wilmington, Del., gave an interesting address on April 5 at Wilmington in connection with the showing of motion pictures of the company's dye works for the first time.

Dr. ALONZO E. TAYLOR, professor of physiological chemistry at the University of Pennsylvania, and JOSEPH S. DAVIS, assistant professor of economics at Harvard, have been named directors of the Food Research Institute, which is to begin work at Stanford University on July 1, under the direction of Dr. C. L. Alsberg, now chief of the United States Bureau of Chemistry.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, April 18, 1921.

The chemical market during the past week has shown no unusual activity. Individual transactions have been mostly of a small nature with a moderate exchange of carlots in some of the more important items. There was a better call noted for medicinal chemicals, but these were sold mostly in small quantities and the volume has not been of large dimensions. The general condition of the market with all its adversities, however, has improved.

Among some of leading factors opinions are quite cheerful regarding the outlook. This no doubt is due to a renewal of buying interest. Although March and April sales have been better than those in preceding months, no one is impressed with the idea that any rapid revival of business can take place. The long drawn-out interval of liquidation, with all its depressing influences, will not permit a quick recovery. There will be temporary intermittent periods of dullness and activity but indications favor an increase more than a decrease in business.

Manufacturers are finding more requests for *caustic soda* and *soda ash*. The latter chemical has been in fair demand for several weeks. Sales have been recorded to Mexico and South American countries and seem to be increasing daily. Domestic textile mills have bought caustic, while a better call for dense ash is being felt from the glass industry. The broadening out of the demand for these two big basic chemicals is very significant, as they are considered by many to be the best barometers to the chemical situation.

There have been reports of purchases of German *caustic potash* at 8@9c. per lb. by prominent consumers. The resale American grade, 88-92 per cent, is to be had as low as 7½@8½c. per lb. Domestic producers are still holding their price up to 12½c., but admit they cannot compete under the relatively high overhead expenses here. Foreign *muriate of potash* is being offered at prices which make it difficult for the domestic makers to sell, and it is understood that plants here have closed down at some points. Foreign *bleach* has been sold in large quantities at 2½c. per lb. N. Y. and *oxalic acid* for shipment from abroad has been offered at 16c. per lb. Paper mills have bought *bleaching powder* at 2¼@2½c. in large drums, although producers are asking as high as 2¾c. *Citric acid* has continued to show strength under higher cable advices from primary points abroad. Several inquiries have reached the market for *arsenic*, but actual business has not been large. *Cyanide of soda* has attracted attention, with the American grade in strong demand.

In general it can be stated that business conditions throughout show many unmistakable signs of improvement. There is in all probability a great deal of liquidation to be accomplished. There is still a vast amount of frozen credit that must be thawed out. The big thing that must be accomplished is the revival of our export business. There is much encouragement noted in Washington at results obtained by the War Finance Corporation on export credit.

GENERAL CHEMICALS

More activity for standard *bichromate of soda* on spot is reported by dealers. Sales went through at 7½c. per lb. and it is doubtful if this price could be shaded on any sizeable quantities. It is stated that a number of 5 and 10 ton lots have been sold and quite a little business could be placed at 7½c. per lb. if sellers would meet these figures. Holders are showing a disposition to tighten up offerings on first appearances of real business. White granular *sal ammoniac* is offered by importers as low as 6½@7½c. per lb. on spot. Makers are holding their prices around 10c. for this grade. *White arsenic* is quoted at 8@8½c. per lb., according to quantity and seller. Business has been slower than the season justified. Recent sales of large lots of *acetate of lime* at \$1.50 per 100 lb. have cleaned up the greater part of stocks offered at this figure, although there still remain some supplies that can be purchased at this level on a firm bid. Openly quoted prices are now around \$2 per 100 lb. The sale of this material at concessions has demoralized the acetic acid market to a great extent. *Muriate of potash* prices are lower on the spot following the offers of heavily distressed lots. Quotations around \$52@55 per ton are heard for prompt delivery. Lower prices are named for imported prussiates. *Red prussiate of potash* is quoted lower at 35@40c. per lb. *Yellow prussiate of potash* is offered freely at 26@28c. per lb. Manufacturers' prices on *soda ash* are held steady at \$1.72½ per 100 lb., basis 48 per cent, f.o.b. works, in single bags. The spot market for domestic material is around \$1.95@2.05 per 100 lb. Resale offerings of *nitrate of soda* are heard lower, in spite of recent advances announced by importers to \$3 per 100 lb. Spot material can be had as low as \$2.50 per 100 lb. It is hard at present to say which course the market will take, although resale stocks are known to be fairly heavy. Resale lots of *formaldehyde* have reached the market at 14c. per lb. and sales have been recorded from this figure up to 15c. It is stated that a considerable amount of small sales has been transacted for agricultural purposes.

COAL-TAR PRODUCTS

Trading in the coal-tar products market during the past week has continued without feature and with very slow demand. Buying has been on a strictly limited scale, with most consumers afraid to lower prices and consequently refusing to take on stocks of any magnitude. Manufacturers are looking forward with great fear to the action at the present session of Congress on the dye question which will probably either make them or break them. Producers seem to be awaiting the word of Congress before junking their plants or initiating extensive building operations.

Prices as a rule have held fairly steady in spite of the lack of interest. Resellers can be found who will cut any price quoted on the slightest show of interest from a prospective buyer, but this attitude is almost entirely absent from the producers' market, where it is felt that concessions should be given only in the face of firm business. Makers have reduced prices on *dinitrobenzene* and *dinitrochlorbenzene*. Producers of *beta naphthol* are holding their quoted price at 40@45c. per lb., although spot lots are still be had as low as 32@34c. per lb. Business has been very slow, and it is understood that while spot stocks are being gradually moved into consuming channels, enough is still available to last for some time at the present rate of movement.

SODIUM COMPOUNDS DURING 1919 AND 1920

According to figures compiled by R. C. Wells of the U. S. Geological Survey, Department of the Interior, the production imports and exports of sodium compounds all increased in 1920 over 1919. The following table shows the complete sales of the individual products sold in the United States in 1919 and 1920:

Product	1919	1920
	Short Tons	
Sodium acetate.....	778	1,020
Sodium bicarbonate.....	134,962	188,906
Sodium bichromate.....	26,526	25,973
Sodium bisulphite.....	11,819	22,059
Soda ash.....	981,054	1,242,490
Salsoda.....	80,090	62,857
Sodium hydroxide.....	311,388	382,680
Sodium nitrite.....	676	140
Sodium phosphate.....	14,760	30,615
Sodium silicate.....	300,138	304,503
Salt cake.....	134,685	184,946
Glauber's salt.....	42,087	44,479
Niter cake.....	83,402	308,638
Sodium sulphide.....	45,448	42,952

Sodium bichromate, nitrate and salsoda were the only compounds that showed considerable decreases in 1920. Several of the compounds made good advances over 1919 and sodium bicarbonate, bisulphite and phosphate made new records.

The following table gives the exports of domestic sodium compounds for 1919 and 1920. It will be noted that good increases were made in 1920. Japan, Canada and Mexico were the leading consumers of our exports:

Product	1919	1920
	Short Tons	
Sodium bicarbonate.....		10,321
Soda ash.....	50,481	8,338
Salsoda.....	5,563	6,015
Sodium chloride.....	119,416	139,278
Sodium hydroxide.....	82,118	112,069
Sodium silicate.....	12,150	17,048
Sodium borate.....		7,163

The Iron and Steel Market

PITTSBURGH, April 15, 1921.

After several weeks in which developments were distinctly unimportant the steel market has in the past week exhibited some very interesting movements. The independents, which had been quoting prices well below the Steel Corporation or Industrial Board prices, advanced their prices slightly and then the Steel Corporation reduced its prices, whereby the corporation and independents are on the same price level, a condition that has existed only occasionally since the period of Government control.

PRICES IN DETAIL

By an announcement made late on April 12 the Steel Corporation reduced its prices as follows: Bars, from 2.35c. to 2.10c.; shapes, from 2.45c. to 2.20c.; plates, from 2.65c. to 2.20c. Nails were reaffirmed at \$3.25, base, per keg, while plain wire was set at 3c. That had been the Industrial Board price, but in August, 1919, the corporation had advanced to 3.25c. Tin plate was reduced from \$7 to \$6.25, per base box, 100-lb. A week ago independent prices were 2c. on bars and 2.10c. on shapes and plates, in carload lots, while concessions below these prices were obtainable on larger lots. Nails had been \$3 in the independent market.

Yesterday the American Sheet & Tin Plate Co. decided upon its new prices for sheets, blue annealed being reduced from 3.65c. to 3.10c., black sheets from 4.35c. to 4c. and galvanized sheets from 5.70c. to 5c. The independent market a week ago was 2.80@2.90c. on blue annealed, 3.75c. on black and 4.75@4.80c. on galvanized.

Tubular goods, hoops and a number of other commodities remain to be acted upon by the Steel Corporation.

WAGES

With these reductions in prices the Steel Corporation does not reduce wages. The independents have made various reductions, beginning early last December, and in general are paying rates about 20 per cent below the old scale, maintained by the corporation. The corporation had been expected to reduce wages when it should reduce prices, but the present reductions are not as great as the corporation was expected eventually to make. Probably the corporation had hoped for a time that eventually one single reduction could be made that would put the market on a stable basis for a long period, but that plan had to be abandoned. Also, the corporation had been working on plans to eliminate the 12-hour day, it being presumably the intention to make the change in working conditions at the same time as the wage rates were changed, and this change is likewise deferred.

OPERATIONS AND ORDERS

The Steel Corporation's operations are now at about 40 per cent, on the basis of ingot production to capacity, having decreased from an average of 90 per cent in January. Independent mill operations are now at about 35 per cent of capacity. Practically all reports and estimates in the trade have understated the rate of independent mill operations since the first of the year, this being perhaps a psychological phenomenon. There is good reason to believe the independents operated at about 30 per cent in both January and February and at about 32 per cent in March.

The reductions by the Steel Corporation are likely to bring the corporation a good batch of "releases" against suspended orders and of specifications against contracts, whereby corporation operations may increase somewhat in the next few weeks, say to 50 per cent. Report has it that in advancing their prices the independents secured closing of a number of orders on quotations they had outstanding, and thus the independents may run slightly better in the next few weeks, without booking much additional business now.

It is idle, of course, to expect the price reductions of the Steel Corporation and the equalization in the market to produce much if any additional consumption of steel. A rough classification is that steel is bought by railroads for their own use, by investors for construction purposes, and by manufacturing consumers for making into wares which they sell. As to the railroads, they cannot be interested, since their present position is that they cannot pay for all the rails they had already ordered for this year. As to investors, they are waiting on better financial conditions and lower wage costs in construction work. As to manufacturing consumers, they must sell their wares if they buy steel, whatever the price of the steel.

PIG IRON

The pig iron market remains stagnant. There are stocks of basic iron in the hands of steel works which the steel producers would be willing to sell. Although only about a score of merchant blast furnaces are in operation in the whole country, there are merchant stocks of considerable size, since many furnaces accumulated iron before they went out. The foundries have been reducing their stocks, but their operations appear to have decreased materially in the past few weeks. Quotations, largely nominal, remain at \$25 for bessemer, foundry and malleable, at \$23 for basic, f.o.b. valley furnace, freight to Pittsburgh being \$1.96.

COKE

It is learned that the recent sale of a round block of Connelville furnace coke to the furnace at Portsmouth, Ohio, was at \$3.50 instead of at \$3.75, the price first reported, and another furnace interest has since bought about 1,000 tons at \$3.50, so that the market seems established at that figure, a price as low as can be expected and representing a very fair liquidation in this item of the cost of making pig iron.

Nickel salt, double.....lb.			.13 - .13½	
Nickel salt, single.....lb.			.14 - .14½	
Phosgene (see carbonyl chloride).....lb.				
Phosphorus, red.....lb.	.45	.46	.47 - .50	
Phosphorus, yellow.....lb.			.35 - .37	
Potassium bichromate.....lb.	.12	.12½	.12½ - .13	

	Carlots	Less Carlots
Potassium bitartrate (cream of tartar) . . . lb.	\$. . . - \$. . .	\$0.30 - \$0.35
Potassium bromide, granular . . . lb.	. . . - . . .	.20 - .40
Potassium carbonate, U. S. P. . . lb.	.35 - .40	.45 - .50
Potassium carbonate, crude . . . lb.	.06½ - .07	.08 - .09
Potassium chlorate, crystals . . . lb.	.07½ - .08	.09 - .14
Potassium cyanide . . . lb.	. . . - . . .	.32 - .35
Potassium hydroxide (caustic potash) . . lb.	.08 - .08½	.09 - .10
Potassium muriate . . . ton	52.00 - 55.00	. . . - . . .
Potassium iodide . . . lb.	. . . - . . .	2.75 - 3.00
Potassium nitrate . . . lb.	.09½ - .09½	.10 - .12½
Potassium permanganate . . . lb.	.35 - .37	.39 - .40
Potassium prussiate, red . . . lb.	.35 - .37	.38 - .40
Potassium sulphate, yellow . . . lb.	.26 - .27	.28 - .29
Potassium sulphate (powdered) . . . per unit	. . . - . . .	1.75 - 1.80
Rochelle salts (see sodium potas tartrate)	. . . - . . .	. . . - . . .
Salammoniac (see ammonium chloride)	. . . - . . .	. . . - . . .
Sal soda (see sodium carbonate)	. . . - . . .	. . . - . . .
Salt cake . . . ton	. . . - . . .	32.00 - 34.00
Silver cyanide . . . oz.	. . . - . . .	1.30 - 1.35
Silver nitrate . . . oz.	. . . - . . .	.39 - .40
Soda ash, light . . . 100 lb.	1.95 - 2.10	2.15 - 2.40
Soda ash, dense . . . 100 lb.	2.20 - 2.30	2.40 - 2.60
Sodium acetate . . . lb.	.04½ - .05	.05½ - .06
Sodium bicarbonate . . . 100 lb.	2.50 - 2.60	2.70 - 3.00
Sodium bichromate . . . lb.	.07½ - .08	.08½ - .08½
Sodium bisulphate (nitre cake) . . . ton	5.00 - 5.25	5.50 - 6.50
Sodium bisulphite powdered, U.S.P. . . lb.	.05½ - .05½	.05½ - .06
Sodium borate (borax) . . . lb.	.06½ - .06½	.07 - .07½
Sodium carbonate (sal soda) . . . 100 lb.	1.90 - 2.00	2.25 - 2.50
Sodium chlorate . . . lb.	.08½ - .09	.09½ - .10
Sodium cyanide, 96-98 per cent . . . lb.	.19 - .20	.21 - .30
Sodium fluoride . . . lb.	.12 - .12½	.13 - .14
Sodium hydroxide (caustic soda) . . . 100 lb.	3.65 - 3.75	3.80 - 4.00
Sodium hyposulphite . . . lb.	. . . - . . .	.03½ - .04
Sodium nitrate . . . 100 lb.	2.50 - . . .	2.60 - . . .
Sodium nitrite . . . lb.	.06 - .06½	.06½ - .07
Sodium peroxide, powdered . . . lb.	.25 - .26	.27 - .30
Sodium phosphate, dibasic . . . lb.	.04½ - .04½	.05 - .05½
Sodium potassium tartrate (Rochelle salts) lb.	. . . - . . .	.27 - .28
Sodium prussiate, yellow . . . lb.	.12½ - .12½	.13 - .13½
Sodium silicate, solution (40 deg.) . . . lb.	1.25 - 1.35	1.40 - 1.50
Sodium silicate, solution (60 deg.) . . . lb.	.03 - .03½	.03½ - .03½
Sodium sulphate, crystals (Glauber's salt) 100 lbs.	1.75 - 2.00	2.25 - 2.50
Sodium sulphide, fused, 60-62 per cent (conc.) lb.	.05½ - .05½	.06 - .06½
Sodium sulphite, crystals . . . lb.	.04 - .04½	.04½ - .05
Strontium nitrate, powdered . . . lb.	.16 - .16	.17 - .18
Sulphur chl. ride, red . . . lb.	.07 - .07½	.07½ - .08
Sulphur, crude . . . ton	20.00 - 22.00	. . . - . . .
Sulphur dioxide, liquid, cylinders extra . . lb.	.08 - .08½	.09 - .10
Sulphur (sublimed), flour . . . 100 lb.	. . . - . . .	2.25 - 3.10
Sulphur, roll (brimstone) . . . 100 lb.	. . . - . . .	2.00 - 2.75
Tin bichloride, 50 per cent . . . lb.	.18 - .19	. . . - . . .
Tin oxide . . . lb.	. . . - . . .	.40 - .42
Zinc carbonate, precipitate . . . lb.	.16 - .18	.19 - .20
Zinc chloride, gran . . . lb.	.11 - .11½	.11½ - .12
Zinc cyanide . . . lb.	.45 - .49	.50 - .60
Zinc dust . . . lb.	.12 - .13	.13½ - .14
Zinc oxide, XX . . . lb.	.08½ - .09	.09½ - .10
Zinc sulphate . . . lb.	.03½ - .03½	.04 - .05

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude . . . lb.	\$1.15 - \$1.25
Alpha-naphthol, refined . . . lb.	1.45 - 1.50
Alpha-naphthylamine . . . lb.	.38 - .40
Aniline oil, drums extra . . . lb.	.20 - .26
Aniline salts . . . lb.	.26 - .29
Anthracene, 80% in drums (100 lb.) . . lb.	.75 - 1.00
Benzaldehyde U.S.P. . . lb.	1.00 - 1.50
Benzidine, base . . . lb.	.90 - 1.00
Benzidine sulphate . . . lb.	.75 - .80
Benzoic acid, U.S.P. . . lb.	.65 - .70
Benzoate of soda, U.S.P. . . lb.	.65 - .70
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.) . . gal.	.25 - .28
Benzyl chloride, 95-97%, refined . . . lb.	.28 - .30
Benzyl chloride, tech. . . lb.	.25 - .27
Beta-naphthol benzoate . . . lb.	3.50 - 4.00
Beta-naphthol, sublimed . . . lb.	.70 - .75
Beta-naphthol, tech . . . lb.	.33 - .45
Beta-naphthylamine, sublimed . . . lb.	2.25 - 2.40
Cresol, U. S. P., in drums (100 lb.) . . lb.	.16 - .18
Ortho-cresol, in drums (100 lb.) . . lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums . . gal.	.90 - .95
Cresylic acid, 95-97%, dark, in drums . . gal.	.85 - .90
Cresylic acid, 50%, first quality, drums . . gal.	.55 - .60
Dichlorobenzene . . . lb.	.06 - .09
Diethylaniline . . . lb.	1.20 - 1.25
Dimethylaniline . . . lb.	.48 - .55
Dinitrobenzene . . . lb.	.32 - .35
Dinitrochlorobenzene . . . lb.	.30 - .30
Dinitronaphthalene . . . lb.	.30 - .40
Dinitrophenol . . . lb.	.35 - .40
Dinitrotoluene . . . lb.	.25 - .27
Dip oil, 25%, tar acids, car lots, in drums . . gal.	.40 - .45
Diphenylamine . . . lb.	.60 - .70
H-acid . . . lb.	1.30 - 1.50
Meta-phenylenediamine . . . lb.	1.20 - 1.25
Monochlorobenzene . . . lb.	.14 - .16
Monochethylaniline . . . lb.	1.75 - 1.85
Naphthalene crushed, in bbls. (250 lb.) . . lb.	.08 - .08½
Naphthalene, flake . . . lb.	.08½ - .09½
Naphthalene, balls . . . lb.	.09½ - .10½
Naphthionic acid, crude . . . lb.	.70 - .75
Nitrobenzene . . . lb.	.12 - .15
Nitro-naphthalene . . . lb.	.30 - .35
Nitro-toluene . . . lb.	.16 - .18
Ortho-amidophenol . . . lb.	3.20 - 3.75
Ortho-dichlor-benzene . . . lb.	.15 - .20
Ortho-nitro-phenol . . . lb.	.75 - .80
Ortho-nitro-toluene . . . lb.	.17 - .20
Ortho-toluidine . . . lb.	.20 - .25
Para-amidophenol, base . . . lb.	1.75 - 1.85
Para-amidophenol, HCl . . . lb.	2.00 - 2.10

Para-dichlorobenzene . . . lb.	.15 - .20
Paranitroaniline . . . lb.	.90 - 1.05
Para-nitrotoluene . . . lb.	.85 - 1.00
Para-phenylenediamine . . . lb.	1.95 - 2.00
Para-toluidine . . . lb.	1.25 - 1.60
Phthalic anhydride . . . lb.	.50 - .60
Phenol, U. S. P., drums (dest.), (240 lb.) . . lb.	.11 - .13
Pyridine . . . gal.	2.00 - 3.50
Resorcinol, technical . . . lb.	1.75 - 1.85
Resorcinol, pure . . . lb.	2.25 - 2.30
Salicylic acid, tech., in bbls. (110 lb.) . . lb.	.22 - .23
Salicylic acid, U. S. P. . . lb.	.21 - .22
Salol . . . lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal. . . gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal. . . gal.	.14 - .16
Sulphanilic acid, crude . . . lb.	.30 - .35
Tolidine . . . lb.	1.35 - 1.45
Toluidine, mixed . . . lb.	.40 - .45
Toluene, in tank cars . . . gal.	.25 - .28
Toluene, in drums . . . gal.	.28 - .31
Xylidines, drums, 100 gal. . . lb.	.40 - .45
Xylene, pure, in drums . . . gal.	.42 - .45
Xylene, pure, in tank cars . . . gal.	.45 - .45
Xylene, commercial, in drums, 100 gal. . . gal.	.33 - .35
Xylene, commercial, in tank cars . . . gal.	.30 - .30

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark . . . lb.	\$0.24 - \$0.26
Beeswax, refined, light . . . lb.	.27 - .28
Beeswax, white pure . . . lb.	.40 - .45
Carnauba, Flora . . . lb.	.68 - .70
Carnauba, No. 2, North Country . . . lb.	.30 - .32
Carnauba, No. 3, North Country . . . lb.	.18 - .19
Japan . . . lb.	.19½ - .19½
Montan, crude . . . lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p. . . lb.	.04 - .04
Paraffine waxes, crude, scale 124-126 m.p. . . lb.	.03 - .03
Paraffine waxes, refined, 118-120 m.p. . . lb.	.04 - .04½
Paraffine waxes, refined, 125 m.p. . . lb.	.04½ - .04½
Paraffine waxes, refined, 128-130 m.p. . . lb.	.05 - .06
Paraffine waxes, refined, 133-135 m.p. . . lb.	.06 - .06½
Paraffine waxes, refined, 135-137 m.p. . . lb.	.06½ - .06½
Stearic acid, single pressed . . . lb.	.11 - .11
Stearic acid, double pressed . . . lb.	.11½ - .11½
Stearic acid, triple pressed . . . lb.	.12 - .12½

Flotation Oils

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Pine oil, steam dist., sp.gr., 0.930-0.940 . . . gal.	\$1.70
Pine oil, pure, dest. dist. . . gal.	1.60
Pine tar oil, ref., sp.gr. 1.025-1.035 . . . gal.	.48
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. . . gal.	.35
Pine tar oil, double ref., sp.gr. 0.965-0.990 . . . gal.	.75
Pine tar, ref., thin, sp.gr., 1.080-1.960 . . . gal.	.36
Turpentine, crude, sp. gr., 0.900-0.970 . . . gal.	1.20
Hardwood oil, f.o.b. Mich., sp.gr., 0.960-0.990 . . gal.	.37
Pinewood creosote, ref. . . gal.	.55

Naval Stores

The following prices are f.o.b. New York for carload lots.

Rosin B-D, bbl. . . 280 lb.	\$4.90 - . . .
Rosin E-I . . . 280 lb.	5.15 - . . .
Rosin K-N . . . 280 lb.	5.50 - . . .
Rosin W. G.-W. W. . . 280 lb.	6.00 - . . .
Wood rosin, bbl. . . 280 lb.	6.25 - . . .
Spirits of turpentine . . . gal.	.58 - . . .
Wood turpentine steam dist . . . gal.	.57 - . . .
Wood turpentine, dest. dist. . . gal.	.56 - . . .
Pine tar pitch, bbl. . . 200 lb.	. . . - 7.00
Tar, kiln burned, bbl. (500 lb.) . . . bbl.	. . . - 14.50
Retort tar, bbl. . . 500 lb.	15.00 - 14.75
Rosin oil, first run . . . gal.	.45 - . . .
Rosin oil, second run . . . gal.	.48 - . . .
Rosin oil, third run . . . gal.	.60 - . . .

Solvents

73-76 deg., steel bbls. (85 lb.) . . . gal.	\$0.41
70-72 deg., steel bbls. (85 lb.) . . . gal.	.39
68-70 deg., steel bbls. (85 lb.) . . . gal.	.38
V. M. and P. naphtha, steel bbls. (85 lb.) . . gal.	.30

Crude Rubber

Para—Upriver fine . . . lb.	\$0.17 - \$0.18
Upriver coarse . . . lb.	.11½ - .12½
Upriver caucho ball . . . lb.	.14 - .14½
Plantation—First latex crepe . . . lb.	.18½ - . . .
Ribbed smoked sheets . . . lb.	.16½ - . . .
Brown crepe, thin, clean . . . lb.	.18 - . . .
Amber crepe No. 1 . . . lb.	.20 - . . .

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls. . . lb.	\$0.08½ - \$0.09½
Castor oil, AA, in bbls. . . lb.	.09½ - .10
China wood oil, in bbls. (f.o.b. Pac. coast) . . lb.	.08½ - .08½
Cocoonut oil, Ceylon grade, in bbls. . . lb.	.09½ - .10
Cocoonut oil, Cochinchina grade, in bbls. . . lb.	.10½ - .10½
Corn oil, crude, in bbls. . . lb.	.07½ - .08
Cottonseed oil, crude (f. o. b. mill) . . . lb.	.03½ - .04
Cottonseed oil, summer yellow . . . lb.	.06 - . . .
Cottonseed oil, winter yellow . . . lb.	.06½ - . . .
Linseed oil, raw, car lots (domestic) . . . gal.	.56 - .57
Linseed oil, raw, tank cars (domestic) . . . gal.	.50 - . . .
Linseed oil, in 5-bbl lots (domestic) . . . gal.	.59 - .60

Olive oil, commercial.....	gal	\$1.90	—	\$2.50
Palm, Lagos.....	lb.	.07	—	.07½
Palm, Niger.....	lb.	.06	—	.06½
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.05½	—	.05¾
Peanut oil, refined, in bbls.....	lb.	.10	—	.10½
Rapeseed oil, refined in bbls.....	gal.	.90	—	.95
Rapeseed oil, brown, in bbls.....	gal.	1.00	—	1.05
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07½	—	.07¾
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04½	—	

FISH

Light pressed menhaden.....	gal.	\$0.45	—	\$0.47
Yellow bleached menhaden.....	gal.	.47	—	
White bleached menhaden.....	gal.	.49	—	
Blown menhaden.....	gal.	.84	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00
Barytes, ground, off color, f.o.b. Kings Creek.....	net ton	22.00	—	26.00
Barytes, crude, 88% @ 94% ba., Kings Creek.....	net ton	10.00	—	17.00
Barytes, floated, f.o.b. St. Louis.....	net ton	26.50	—	28.00
Barytes, crude, first grade, Missouri.....	net ton	10.30	—	
Blanc fixe, dry.....	lb.	.05	—	.05½
Blanc fixe, pulp.....	net ton	50.00	—	60.00
Casein.....	lb.	.14	—	.16
Chalk, domestic, extra light.....	lb.	.05	—	.05½
Chalk, domestic, light.....	lb.	.04½	—	.05
Chalk, domestic, heavy.....	lb.	.04	—	.05
Chalk, English, extra light.....	lb.	.05	—	.07
Chalk, English, light.....	lb.	.05	—	.06
Chalk, English, dense.....	lb.	.04½	—	.05
China clay (kaolin) crude, f.o.b. mines, Georgia.....	net ton	8.00	—	10.00
China clay (kaolin) washed, f.o.b. Georgia.....	net ton	12.00	—	15.00
China clay (kaolin) powdered, f.o.b. Georgia.....	net ton	18.00	—	22.00
China clay (kaolin) crude f.o.b. Virginia points.....	net ton	8.00	—	12.00
China clay (kaolin) ground, f.o.b. Virginia points.....	net ton	15.00	—	40.00
China clay (kaolin), imported, lump.....	net ton	23.00	—	25.00
China clay (kaolin), imported, powdered.....	net ton	30.00	—	35.00
Feldspar, crude, f.o.b. Maryland and North Carolina points.....	gross ton	8.00	—	14.00
Feldspar, crude, f.o.b. Maine.....	net ton	7.50	—	10.00
Feldspar, ground, f.o.b. Maine.....	net ton	21.00	—	23.00
Feldspar, ground, f.o.b. North Carolina.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. N. Y. State.....	net ton	17.00	—	21.00
Feldspar, ground, f.o.b. Baltimore.....	net ton	27.00	—	30.00
Fullers earth, f.o.b. Mines.....	net ton	16.00	—	17.00
Fullers earth, granular, f.o.b. Pa.....	net ton	15.00	—	25.00
Fullers earth, powdered, f.o.b. Fla.....	net ton	18.00	—	
Fullers earth, imported, powdered.....	net ton	24.00	—	27.00
Graphite, Ceylon lump, first quality.....	lb.	.07½	—	.08
Graphite, Ceylon chip.....	lb.	.06	—	.06½
Graphite, high grade amorphous crude.....	lb.	.02½	—	.03
Pumice stone, imported, lump.....	lb.	.04	—	.50
Pumice stone, domestic lump.....	lb.	.05	—	.05½
Pumice stone, ground.....	lb.	.06	—	.07
Quartz (acid tower) first to head, f.o.b. Baltimore.....	net ton		—	10.00
Quartz (acid tower) 1½ @ 2 in., f.o.b. Baltimore.....	net ton		—	14.00
Quartz (acid tower) rice, f.o.b. Baltimore.....	net ton		—	17.00
Quartz, lump, f.o.b. North Carolina.....	net ton	5.00	—	7.50
Shellac, orange fine.....	lb.	.57	—	
Shellac, orange superfine.....	lb.	.60	—	
Shellac, A. C. garnet.....	lb.	.45	—	
Shellac, T. N.....	lb.	.45	—	
Soapstone.....	ton	12.00	—	15.00
Sodium chloride.....	long ton	14.00	—	15.00
Talc, paper-making grades, f.o.b. Vermont.....	ton	11.00	—	20.00
Talc, roofing grades, f.o.b. Vermont.....	ton	8.50	—	13.00
Talc, rubber grades, f.o.b. Vermont.....	ton	11.00	—	18.00
Talc, powdered, Southern, f.o.b. cars.....	ton	10.00	—	14.00
Talc, imported.....	ton	35.00	—	40.00
Talc, California talcum powder grade.....	ton	18.00	—	40.00

Refractories

Bauxite brick, 56% Al, f.o.b. Pittsburgh.....	1,000	160	
Carborundum refractory brick, 9 in. less than earlot	1,000	1250 00	
..... earlot lots	1,000	1100 00	
Chrome brick, f.o.b. Eastern shipping points.....	net ton	80-100	
Chrome cement, 40-45% Cr ₂ O ₃	net ton	45-50	
Chrome cement, 40-45% Cr ₂ O ₃ , sacks, in car lots, f.o.b. Eastern shipping points.....	net ton		55
Fireclay brick, 1st quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	55-60	
Fireclay brick, 2nd quality, 9-in. shapes, f.o.b. Pennsylvania, Ohio and Kentucky works.....	1,000	45-50	
Magnesite brick, 9-in. straight.....	net ton	90	
Magnesite brick, 9-in. arches, wedges and keys.....	net ton	105	
Magnesite brick, soaps and splits.....	net ton	120	
Silica brick, 9-in. sizes, f.o.b. Chicago district.....	1,000	45-55	
Silica brick, 9-in. sizes, f.o.b. Birmingham district.....	1,000	45-55	
Silica brick, 9-in. sizes, f.o.b. Mt. Union, Pa.....	1,000	45-55	

Ferro-Alloys

All f.o.b. Works

Ferr-titanium, 15-18%, f.o.b. Niagara Falls, N. Y.....	net ton	\$200.00	—	\$225.00
Ferrochrome per lb. of Cr. contained, 6-8% carbon, earlots.....	lb.	.15	—	.16
Ferrochrome per lb. of Cr. contained, 4-6% carbon, earlots.....	lb.	.16	—	.17
Ferromanganese, 76-80% Mn, domestic.....	gross ton	85.00	—	90.00
Ferromanganese, 76-80% Mn, English.....	gross ton	85.00	—	90.00
Spiegelisen, 18-22% Mn.....	gross ton	32.00	—	35.00
Ferromolybdenum, 50-60% Mo, per lb. of Mo.....	lb.	2.50	—	
Ferrothion, 10-15%.....	gross ton	50.00	—	55.00
Ferrothion, 50%.....	gross ton	85.00	—	90.00
Ferrosilicon, 75%.....	gross ton	145.00	—	150.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

TEXARKANA—The Southern Acid & Sulphur Co. is planning for the reconstruction of the building of its plant destroyed by fire, April 1, with loss estimated at about \$22,000.

Connecticut

SOUTHINGTON — The Peck, Stow & Wilcox Co., manufacturer of tools has plans under way for the erection of three additions to comprise a 1-story hardening building 67 x 180 ft.; 1-story forge shop, 57 x 100 ft.; and 2-story grinding works, 56 x 156 ft. Pierce & Hutton, Southington, are engineers.

NEW HAVEN — The Columbia Enamel Co. is reported to be planning for the rebuilding of the portion of its plant, recently destroyed by fire.

Florida

MIAMI—The Dexter-Geare Corp. has acquired a local site for the erection of a new plant for the manufacture of monolithic concrete tile products, bricks, etc. Plans are being prepared.

Georgia

COVINGTON—Fire, April 8, destroyed a portion of the plant of the Covington Cotton Oil Co., with loss estimated at close to \$150,000, including machinery.

Illinois

CENTRALIA—The American Rubber Co., 1526 South Wabash Ave., Chicago, has awarded a contract to the Welch-McCarthy Constr. Co., 56 W. Washington St., Chicago, for the erection of its proposed new 2-story plant at Centralia, 80 x 360 ft., estimated to cost about \$150,000 with machinery. A power plant will also be constructed.

ARGO—The Corn Products Refining Co. has resumed operations at its local grinding plant, following a shut-down for several weeks. It is said that work will be resumed at the Pekin (Ill.) plant at an early date.

PEORIA—The United Paperboard Co. is completing plans for the rebuilding of its local plant, recently destroyed by fire. The new factory is estimated to cost about \$200,000 with machinery. C. E. Foster is secretary.

Maryland

FROSTBURG—The Big Savage Fire Brick Co. will resume work at once on its expansion program inaugurated in February and later discontinued. The work will include the erection of two brick and steel buildings, 150 x 300 ft. and 150 x 200 ft.; the first will be used for kiln service, storage and other features of operation, and the other for manufacturing purposes. Considerable new machinery and equipment will be installed, including 12 furnaces. The plant, on completion, will occupy about 1½ acres of ground. Employment will be given to about 100 extra operatives and it is proposed to increase production by 50,000 firebrick per day. The extension is estimated to cost about \$150,000. D. A. Benson is vice-president and treasurer.

BALTIMORE—The Cook-Nut Corp., Purity Bldg., Lexington and Paca Sts., has arranged for a stock issue of \$175,000, the proceeds to be used for the erection of its proposed new local plant for the manufacture of lard substitutes, cooking oils, etc. The plant will be located in the Canton section, and will be 4-story, 80 x 100 ft., estimated to cost \$125,000. Bids for erection will soon be asked. Walton R. Spruill is president, and John L. Swope, vice-president.

FAIRFIELD—The Prudential Oil Co. has commenced the erection of a number of additions to its plant.

Massachusetts

TAUNTON—The Weir Stove Co. is having plans prepared for the erection of a new 2-story foundry addition on Fourth St., 77 x 77 ft., estimated to cost about \$25,000. J. R. Anthony is head.

BOSTON—The American Glue Co., operating a number of plants in New England and in other sections for the manufacture of glue, gelatines, chemicals, etc., has arranged for a note issue of \$1,500,000, the proceeds to be used in connection with general operations.

Michigan

BATTLE CREEK—The American Stamping Co., manufacturer of stamped metal products, has awarded a contract to F. B. Cole, Battle Creek, for the erection of its proposed new 1- and 2-story plant, 110 x 225 ft. E. R. Sherman is president.

Minnesota

ST. PAUL—The Northwestern Spring Mfg. Co. is planning for the rebuilding of the portion of its plant, located in the Columbia Heights section, destroyed by fire, March 25, with loss estimated at about \$100,000, including equipment.

Nebraska

ANTIOCH—Fire April 2 destroyed a section of the plant of the American Potash Co. with loss estimated at about \$500,000 including machinery.

New Jersey

NEWARK—The Zeller Laquer Co., recently organized, has acquired a plant at Irvington, consisting of a number of 1-story buildings on a 3½-acre site, for the establishment of a new plant. The factory aggregates about 28,000 sq. ft. of floor area. The company is headed by Gustav Zeller and Richard Zeller, formerly connected with the Egyptian Lacquer Co., 5 E. 40th St., New York.

TRENTON—The Star Porcelain Co., Muirhead Ave., manufacturer of electrical porcelain specialties, has completed plans for the erection of a 2-story addition 30 x 100 ft. to cost about \$10,000. Herbert Sinclair is head.

TRENTON—The Ewing Rubber Co., Homan Ave., is planning for the rebuilding of the portion of its plant recently destroyed by fire.

New York

SYRACUSE — The By-Products Coke Corp., Milton Ave., is planning for a bond issue of \$4,000,000 and stock issue of \$5,000,000, to be used in connection with general operations.

ITHACA—The Board of Trustees, Cornell University, will soon take bids for the construction of a new 4-story chemical laboratory and instruction building, 70 x 270 ft., to be located at East Ave. and Rockefeller Hall, and estimated to cost about \$2,000,000. Gibb & Waltz, 110 North Tioga St., Ithaca, are architects.

BUFFALO—The Williams Gold Refining Co., 2978 Main St., will take bids at an early date for the erection of a 1-story addition, 50 x 60 ft., estimated to cost about \$12,000.

North Carolina

HAMLET—The Poole Turpentine Distilling Co. is planning for the erection of a new plant for turpentine and byproducts production.

Ohio

CLEVELAND — The Collinwood Shale Brick & Supply Co. has leased a plant from the Medal Paving Brick Co. for a period of five years, and plans for the operation of the property. The lease begins at a yearly rental of \$65,000 and terminates at \$100,000.

BRILLIANT—The Crystal Shade Co., Wheeling, W. Va., is planning for the immediate operation of a local glass-manufacturing plant recently acquired. Employment will be given to about 50 men for initial production.

Pennsylvania

PHILADELPHIA — The Federal Container Co. 25th and Locust Sts. manufacturer of corrugated paper containers, etc., has awarded a contract to W. W. Lindsay & Co., Harrison Building, for the erection of a new 2-story plant at 56th St. and Pashall Ave., 82 x 302 ft., estimated to cost about \$150,000 with machinery.

PHILADELPHIA — Fire, April 4, destroyed a portion of the fertilizer manufacturing plant of the Savannah Co., 37th and Tasker Sts., with loss estimated at about \$12,000.

BANGOR—The Bangor Paper Box Co. will take bids at once for the erection of a new 3-story plant, 35 x 100 ft., estimated to cost about \$25,000. M. H. Wheeler is head.

PHILADELPHIA—The Sun Co., Finance Bldg., operating local oil refineries, has arranged for a bond issue to total \$6,000,000, to be used in connection with general operations. J. Howard Pew is president.

PHILADELPHIA—The W. J. McCahan Sugar Refining Co., Front and Chestnut Sts., has taken title to property at 101-105 South Front St., for a consideration of \$75,000, to be used in connection with its local operations.

Oregon

PORTLAND — The Willamette Iron & Steel Co. has perfected plans for the erection of its proposed new plant on the shipyard property formerly occupied by the Foundation Co. The works will consist of a number of buildings, estimated to cost about \$250,000 with machinery. Permits to cover initial features of the project have been issued.

Tennessee

ELIZABETHTON—The Watauga Extract Co. is said to be planning for the rebuilding of the portion of its local plant recently destroyed by fire, with loss estimated at about \$15,000.

MEMPHIS — The Missouri Portland Cement Co. will complete a sand and gravel producing plant on Chelsea Ave., and put it into operation within the next sixty days. The plant will be equipped with an electrically-driven steel dredge. Offices are in the Union & Planters Bank Bldg., Memphis.

Texas

SAN ANTONIO—The International Petroleum Co. has awarded a contract to the Southern Steel Construction Co., San Antonio, for the completion of its oil refinery on South Presa St., near the city, recently purchased, in incomplete condition, from the Rogers Refinery. The plant will represent an investment of \$100,000, and will have an initial capacity of 1,000 bbls. of crude oil daily.

BRECKENRIDGE—The Consumers' Water & Gas Co., recently incorporated with a capital of \$500,000, is considering the erection of a new absorption gasoline plant. E. G. Dawes and O. L. Barr head the company.

TEXARKANA — The Diamond Spear Chemical Co., recently incorporated with a capital of \$40,000, will operate a local plant for the manufacture of chemical products. Clifton Spear and B. L. Mahon head the company.

West Virginia

CHARLESTON — The American Clay Products Co. has commenced the erection of a new plant in the vicinity of Teays, W. Va., for the manufacture of hollow tile and other burned clay products. The company recently increased its capital from \$5,000 to \$50,000 for expansion. C. L. Rice is president and treasurer.

ST. MARYS—The Western Glass Co. is arranging for the early resumption of operations at its plant, following a shut-down of about three months. It is proposed to develop normal output on a gradual scale.

NEW MARTINSVILLE—The Universal Concrete Produces Co. has commenced the construction of a new plant, 70 x 120 ft., for the manufacture of concrete blocks, bricks and kindred specialties.

WHEELING—The Northern Wheeling Bottle Co. will soon resume production at its local plant, giving employment to about 200 men.

Capital Increases, Etc.

THE SHASTA ZINC & COPPER CO., San Francisco, Cal., has filed notice of increase in capital from \$20,000,000 to \$25,000,000.

THE STANDARD BRICK CO., Charleston, W. Va., has filed notice of increase in capital from \$10,000 to \$150,000. Fred M. Staunton is president.

THE PEERLESS STAMPING CORP., Ypsilanti, Mich., has filed notice of increase in capital from \$10,000 to \$60,000.

THE APEX CHEMICAL CO., 61 Park Row, New York, N. Y., has filed notice of increase in capital from \$10,000 to \$60,000.

THE PRODUCERS' CHEMICAL CORP., 201 B'way, New York, N. Y., has filed notice of dissolution under state laws.

THE HURON CLAY PRODUCTS CO., Crosswell, Mich., has filed notice of increase in capital from \$50,000 to \$70,000.

THE EASTERN OIL REFINING CO., a Delaware corporation, has filed notice of organization to operate in New York with a capital of \$5,000,000. E. J. Suor, Buffalo, is corporate representative.

THE AMERICAN PAPER TUBE CO., Woonsocket, R. I., has filed notice of increase in capital from \$100,000 to \$600,000.

THE BRIGGS CO., Lansing, Mich., manufacturer of brick and other burned clay products, has filed notice of increase in capital from \$150,000 to \$400,000.

THE D'ARCY SPRING CO., Kalamazoo, Mich., manufacturer of steel springs, etc., has filed notice of increase in capital from \$75,000 to \$1,000,000.

New Companies

THE SARDONYX MFG. CO., Dallas, Tex., has been incorporated under Delaware laws with a capital of \$50,000 to manufacture soaps and kindred products. The incorporators are J. E. Bryant, E. Morley Page, Dallas; and William H. Herring, Houston, Tex.

THE NEW ENGLAND PAPER MILLS, INC., New York, N. Y., has been incorporated with a capital of \$25,000 to manufacture paper products. The incorporators are A. Braunstein, J. Hillman and M. Leffert, 198 B'way.

THE MIDDLESEX RUBBER CO., Reading, Mass., has been incorporated with a capital of \$50,000 to manufacture rubber products. George E. Jeandheur, 1277 Commonwealth Ave., Brighton, Mass., is president and treasurer; Michael F. Culliney and H. M. Clifford, Reading, are directors.

THE B. L. W. CO., 1542-44 Milwaukee Ave., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture leather goods. The incorporators are Louis Winkler, David Berger and Samuel La Bow.

THE STILLWATER PAPER MILLS, INC., Stillwater, Pa., has been incorporated with a capital of \$10,000 to manufacture paper goods. F. N. Hamlin is treasurer.

THE ADRIAN CHEMICAL CO., Pittsburgh, Pa., has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical byproducts. The incorporators are R. D. King, F. M. Adrian and George H. Wood, Pittsburgh.

THE FALCO CHEMICAL CORP., Buffalo, N. Y., has been incorporated with a capital of \$10,000 to manufacture chemicals and kindred products. The incorporators are T. Locon, F. H. Cofall and S. B. Pfeifer, Buffalo.

THE TIDEWATER GLASS CO., Wheeling, W. Va., has been incorporated with a capital of \$250,000 to manufacture glass products. The incorporators are George A. Blackford, and A. Seamon, Wheeling; and A. J. Gilleland, Martins Ferry, O.

THE WARREN BRICK & TILE CO., Detroit, Mich., has been incorporated with a capital of \$100,000 to manufacture brick, tile and other burned clay products. The incorporators are Abraham Budnitzky, Abraham Nordoloff and Louis Chernoff, 80 Glendale Ave.

THE PARIS PAPER BOX CO., Boston, Mass., has been incorporated with a capital of \$25,000 to manufacture paper containers and kindred products. The incorporators are E. Mochedlofer, Benjamin Nigrosh and Max Nigrosh, 183 Walnut St., Roxbury, Mass.

THE LEVIATHAN OIL CORP., Lockport, N. Y., has been incorporated with a capital of \$250,000 to manufacture refined oil products. The incorporators are A. A. Gloetzner, A. E. Lee and R. R. Singer, Lee, Ward & Riley, F. & M. Bank Bldg., represent the company.

THE AMERICAN PHOSPHATE CORP., New York, N. Y., has been incorporated with a capital of \$5,000 to manufacture fertilizers and kindred products. The incorporators are P. J. Dobson, L. N. Martin and W. J. Eldredge. Foley & Martin, 64 Wall St., represent the company.

THE INTER-OCEAN PAPER & BAG CO., 350 North Clark St., Chicago, Ill., has been incorporated with a capital of \$30,000 to manufacture paper products. The incorporators are Edward J. Sexauer, Samuel J. Howe and Bernhardt J. Ness.

THE SERVICE HEAT-TREATING CO., Detroit, Mich., has been incorporated with a capital of \$5,000 to manufacture heat-treating equipment for steel and other metals. The incorporators are Herbert F. Halpin, Robert Barker and Charles Reinacker, 2243 Hilliger Ave.

THE NATIONAL CHINA CO., Huntington, W. Va., has been incorporated with a capital of \$10,000 to manufacture chinaware products. The incorporators are S. Heimy, L. Leibovitz and L. Slutsky, Huntington.

THE EL GOBIERNO PETROLEUM CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are Norman Bridge, J. C. Anderson and Olin Wellborn, Jr., Los Angeles.

GREENWALD BROS., INC., New York, N. Y., has been incorporated with a capital of \$6,000 to manufacture chemicals and affiliated products. The incorporators are M. Greenwald, E. S. Rifkin and A. Leichter, 141 B'way.

A. LUSSKIN, INC., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are A. Lusskin, I. H. Kessler and I. Miller. H. A. Harkavy, 299 B'way., represents the company.

THE NASHVILLE ENAMELING CO., 42d Ave. and Charlotte Pike, Nashville, Tenn., has been incorporated with a capital of \$50,000 to manufacture enamelware products. The incorporators are Valentine Taylor, John R. Burrows and Herman Spitz, Nashville.

THE DETROIT PORUS INNER TUBE CO., Hamtramck, Mich., has been incorporated with a capital of \$100,000 to manufacture automobile tubing, rubber mats and other rubber products. The incorporators are Frank Moons and George S. Holstein, 3128 Elmwood Ave., Detroit.

THE GARDNER PAPER CO., Providence, R. I., has been incorporated with a capital of \$100,000 to manufacture paper products. The incorporators are LeRoy N. Gardner and Albert A. Adams, Providence.

THE AURORA STEEL & STAMPING CO., 375 High St., Aurora, Ill., has been incorporated with a capital of \$25,000 to manufacture steel and other stamped metal products. The incorporators are Benjamin P. Alschuler, Ralph C. Putnam and Glenn T. Johnson.

THE DUNMORE DRUG MFG. CO., Dunmore, Pa., has been incorporated with a capital of \$40,000 to manufacture chemicals, drugs and affiliated products. The incorporators are M. J. Dempsey, W. B. Weisberger and John J. Byrne, Dunmore.

THE STANDARD SHALE CHEMICAL CO., Columbus, O., has been incorporated with a capital of \$10,000,000 under Delaware laws to manufacture chemicals and byproducts. The incorporators are Selden D. Maddox, Columbus; W. E. Tochey, Middletown, O., and Louis M. Day, Chillicothe, O.

THE JET OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are W. A. Brophy and S. W. Warrington, Los Angeles; and J. G. Burgess, San Diego, Cal. H. P. Goodwin, 233 Title Insurance Bldg., represents the company.

THE PENETRO CHEMICAL CO., Atlantic City, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are Thomas J. and Raymond J. McCaffrey, and John B. Heon. Dr. L. H. English, 130 South Maryland Ave., represents the company.

THE R. & W. PAPER BOX CO., New York, N. Y., has been incorporated with a capital of \$5,000 to manufacture paper boxes and containers. The incorporators are R. H. Blum, E. Kaplan and A. Feldman, 283 Division St.

THE CHEBOYGAN TILE & BRICK CO., Cheboygan, Mich., has been incorporated with a capital of \$75,000 to manufacture brick, tile and other burned clay products. The incorporators are W. L. Hagadorn, A. M. Gerow and J. H. Clune, Cheboygan.

THE HUNTINGTON NATIONAL OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are S. C. J. R. and M. D. Woodward, and C. C. Closson, Los Angeles.

THE CAIRO COTTON OIL MILL, INC., Upper Sycamore St., Cairo, Ill., has been incorporated with a capital of 200 shares of stock, no par value, to manufacture oil products. The incorporators are M. L. and F. P. Fox, and F. L. Short.

THE CARAMEL COLOR CO. OF AMERICA, INC., Brooklyn, N. Y., has been incorporated with a capital of \$5,000 to manufacture chemicals, colors and affiliated products. The incorporators are R. Adler, B. Levine and A. S. Fischer, 3957 W. 7th St.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY will hold its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters will be at the Hotel Rochester.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its spring meeting at Atlantic City April 21 to 23 inclusive. Headquarters will be at the Hotel Chalfonte.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN WELDING SOCIETY will hold its annual meeting April 27 to 30 in the Engineering Societies Building, New York City.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

HARVARD ALUMNI CHEMISTS' ASSOCIATION will meet Tuesday noon, April 26, at Rochester, N. Y., for luncheon.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stetters Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month, except June, July, August and September.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: April 22, Society of Chemical Industry, joint meeting with American Electrochemical Society, Société de Chimie Industrielle and American Chemical Society; May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Unconscious Disarmament

AT THE dinner given by the members of the Technical Association of the Pulp and Paper Industry Prof. MARSTON T. BOGERT of Columbia spoke of "Unconscious Disarmament," and the idea is worth remembering.

Suppose we go ahead and build big battleships that cost \$30,000,000 apiece but hold fast to the familiar conservative advice and let chemical industry piffle out. Suppose we heed the demands for their masters of such legislators as senator MOSES and let General PEYTON C. MARCH have his own way and give up our Chemical Warfare Service and organize the defense of our nation without the aid of chemistry. We can have a great navy and big guns and brass bands, and many soldiers drilling, and still be disarmed. We can be disarmed despite immense army and navy appropriations.

In some of the later bombardments of the war as high as 80 per cent of the shells shot contained gas. The German gas, all of it, was made in their dyeworks. The Germans are a war-lusty people, and their present inadequate licking has not taken the taste of it from them. As individuals nearly every one knows Germans who are honest and loyal and trustworthy to the end. As a nation they have shown themselves to be without honor, and that is the reason why, to use a German expression, they are *in Verruf*.

They have destroyed the French coal mines, turning them into great submarine lakes and filling their entrances with explosives, so that the greatest of them cannot be operated before 1932. But even without Silesia the Germans have far more coal than England and Wales. Their facilities for fixing nitrogen, present and under construction, are about twice their industrial requirements. The one use for these products besides industry is munitions of war. Their external debt is forty million dollars, while that of France is six billion dollars. They have no devastated areas, whereas that of France is the size of Massachusetts, Connecticut and Rhode Island combined, and before the war it provided one-fifth of the nation's income from taxes. Even if we do say it with a tinge of jealousy, the Germans' consumption of champagne is said to be greater than that of any other country, and champagne does not indicate poverty. The bets registered at one race meet are reported to have equaled the sum collected in the United States to relieve the starving children of Germany. If the Germans had fed their children and the Americans had bet on their racehorses on this one occasion, the results, so far as the starving children are concerned, would have been the same. We used to think we could make millionaires pretty fast in this country, but they seem to be beating us at that game, too.

Now, as Dr. BOGERT pointed out, the club gave way to

the bow and arrow; the arrow to the musket; the iron-clad succeeded the wooden battleship, and now the airplane and the submarine have succeeded the dreadnought. You do not need to strike a ship with a bomb to destroy it. A gas torpedo dropped to windward will kill everybody aboard. A thousand pounds of TNT dropped near a battleship will sink it. Chemical warfare, which has only just begun, makes it so easy to destroy a battleship and its crew that the question is arising whether it is worth while to build them at \$30,000,000 each. It is not even certain that the biggest navy will control the sea.

Let's take a little lesson from history. In the third century B.C. the Carthaginians ruled the Mediterranean. They had triremes and quinqueremes—i.e., galleys with, respectively, three and five banks of oars. Their naval maneuvers consisted chiefly in ramming the ships and breaking the oars of the enemy. In order to quell the piracy that prevailed they established a station at Messina, and that offended the Romans, and so the Punic wars began. The Romans built galleys provided with a boarding bridge with hooks, called a *corvus*, and manned their ships with soldiers. This was new and unconventional, and the Carthaginian naval authorities knew better. They were conservative in sea warfare and would not adopt newfangled notions. So they lost their navy, and in the end they lost their country so completely that the descendants of their people to this day live in darkness and even their skins are black. They were disarmed at sea by the *corvus*.

We may not like poison gas or submarines, but they are here and the Germans are masters of the arts of making them and using them. Surely we don't want to use them, and we hope it may never be necessary. But if the Germans can break up Poland and Czecho-Slovakia and get Russian man power to fight for them, they are even now prospectively the physical masters of the world.

There are also micro-organisms that are destructive, and it may be recalled that there was an official exportation of anthrax bacilli from Germany into Roumania during the war. It seemed a little too hazardous, even for the Germans, but there is the whole field of biochemistry to call on for means of destruction that has not been brought into general use as yet. We do not fear elephants and lions and tigers or any big animals, but those that are infinitely small have us beaten as soon as they are introduced. And suppose the German people, feeling strong again, should find that the whole world is unwilling to let them dominate. This may be construed into an attack upon the German Will—and we know that the Germans have no reservations in war.

There is just one way, and only one way, to insure against any enemy, and that is—not to think we are doing great things because we spend big money, and

not to heed the peeps of Senators and Congressmen who represent special interests, but to insist upon it constantly, urgently and without any argument or pettifoggery, that this country must and shall lead in science. Therein is our safety. It is the only physical guardian of our heritage of freedom. We owe this to the coming generations. To pass the dye bill is the first step.

Developments in the Army's Nitrogen Policy

ON THE subject of national nitrogen preparedness and the disposition of the Government's Nitrate Plant No. 2 at Muscle Shoals, this journal has consistently supported the position and advocated the views of the Chief of Ordnance and the officers of the Nitrate Division. This broad policy was originally determined and is still maintained on the ground that national welfare is paramount to private interest. We believe the position is sound, notwithstanding partisan pleading to the contrary. Nitrate Plant No. 2 was built for the Army in an emergency, and the cyanamide process was adopted because it was then, as it still is, the only process of nitrogen fixation which has been brought to commercial utility in this country. It was recognized when the plant was built that its disposition after the war might be a delicate problem involving a conflict of opinion between public and private interest. But having been built for the Army, and being subsequently regarded by the Army as necessary to the national defense, it seemed rational to take steps to secure it for that purpose.

After the Armistice, when the Army's plans for future preparedness assumed a magnitude commensurate with its recent experience in the World War, it seemed advisable and necessary to advocate continued Government ownership and operation of Nitrate Plant No. 2. It is true that this plan would have involved production of fertilizer materials, but that would have been only an incidental result and not the primary purpose. There were much broader plans behind the project looking toward research and experimentation that would give the United States the premier position in nitrogen fixation instead of the less than subordinate rank it now holds. Furthermore it was the avowed purpose of the Chief of Ordnance to control and operate the plant only until private capital should establish in this country a nitrogen-fixation industry on which the Army could rely in case of emergency. That purpose still prevails. All this, however, is now a matter of history, for the plan was defeated in Congress through the intervention of private interests. Even had it been acted on favorably, the legislation would have been ineffective in view of the decision of Congress to discontinue work on the Wilson dam and power plant at Muscle Shoals, on the completion of which the economic operation of the nitrate plant is dependent.

All of these items, together with a recent revision of the plans of the Army for raising and equipping a reserve force and putting it into action, lend a new aspect to the whole matter. Contemplating a smaller reserve force, it is felt that the present supply of Chilean nitrate will suffice for the production of munitions as rapidly as men can be trained and equipped—*provided* that Nitrate Plant No. 2 be put in stand-by condition and held ready for emergency. The first year's production of this plant would augment the Chilean nitrate reserve and suffice until new plants could be built. And

probably the latter could be accomplished as rapidly as further forces could be raised, trained and equipped. In view of these revised plans it is unnecessary to insist on Government operation of the plant at Muscle Shoals, but merely to put it in stand-by condition and hold it at the disposal of the Army.

There remain two other phases of the nitrogen problem which are of national concern: the completion of the Wilson dam and the continuance of the work of the Fixed Nitrogen Research Laboratory at American University. With the Secretary of War rests the future of these projects. As to the first he has announced that if he can find private business interests that will assure him of the commercial utility of the dam and power plant and will agree to take it over and operate it when completed, he will recommend to Congress the appropriation of the necessary funds, estimated at about \$30,000,000, for its completion. If he cannot assure himself on these points, he will not recommend an appropriation.

With the research work, however, we are more concerned. The laboratory has done excellent work and is well manned and directed. Its research has been of value not only to the Government but also to the future success of a private nitrogen industry in the United States. Some of its experiments have been more exhaustive and complete than any heretofore conducted in this country. Agriculture as well as warfare will profit from its investigations. Considering the fact that money is already available for work beyond July 1, to which date Secretary BAKER authorized the laboratory to continue its investigations, there appears to be no reason why the place should be closed. To do so would mean the great loss always incidental to scattering an excellent staff. We believe, therefore, that Secretary WEEKS should by all means authorize the continuance of the research laboratory. In a recent interview by the editor of CHEMICAL & METALLURGICAL ENGINEERING he was asked as to his policy in this matter and replied that while he had not as yet reached a decision, his "personal inclination would be to continue the work." This we hope will be his final decision.

Why Hire A Chemist?

THE Research Information Service of the National Research Council has just received a communication from a chemical manufacturing concern, the name of which we shall not mention for rather obvious reasons, which says: "We would appreciate it, and thank you, if you would kindly furnish us with a working formula for the manufacture of meta-nitraniline. We are aware that the base of this product is dinitrobenzene, but if you could furnish us with a formula for the manufacture of the above product from nitrobenzene and then follow as nearly as possible the continuation for the finished product of the meta, we would appreciate it." Of course they would!

This company, which, by the way, advertises itself as a firm of "manufacturing chemists," goes on to say that it has good information from certain industrial text books, but finds that these books do not give "clearly" what the company wants. It even has the frankness to say, "We are aware that if we had a qualified chemist this product could be worked out, as we know there is not much to it."

It is gratifying to learn that the Research Council in replying to this inquiry with appropriate frankness told

this company that it should go and hire a chemist or at least a consulting chemist for this particular task.

Absurdity reaches a maximum when a firm undertakes so complicated a task as dyestuff manufacture without the assistance of experienced and expert chemists. It is little wonder that American dyes at times come into bad repute if they are made by this sort of "manufacturing chemists." The firm no doubt can conduct the commercial end of the business which it advertises as "importer and dealer in dyestuffs and chemicals" without the intimate control that manufacturing processes require of a chemist. But until it, and others like it, learn to keep out of the manufacturing business unless it engages qualified employees to direct the work we can expect serious results for the industry as a whole.

Universities And Research

CIRCUMSTANCES prevented editorial discussion last week of the thoughtful contribution of Messrs. HOSKINS and WILES to the unsettled question of the relation of our universities to scientific and industrial research. Different solutions of the problem are being sought and advocated in different institutions, and we have recently added our own views in the matter, which are to the effect that the university laboratory is the place for scientific rather than industrial research, and that the consulting engineer rather than the university industrial fellow is the logical agency for the investigation of the technical problems of industry. Broad exceptions may be made to this general policy, but in its essence we believe it to be sound. Nevertheless we are glad to have the opposing views of Prof. ROBERT E. WILSON, director of the Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology, which we publish elsewhere in this issue.

As we read the communications of Messrs. HOSKINS and WILES and Prof. WILSON it seems likely that we can reach agreement on several points: First, that the appropriate place for pure science research is the university laboratory; second, that we need a great increase in this kind of research for the ultimate benefit and use of industry; third, that the university needs financial support for the execution of this work; and fourth, that since industry is the ultimate beneficiary of the results, it is the logical source of the needed support. At this point, however, our paths diverge, and the crux of the matter becomes the *modus operandi* whereby industry shall be induced and enabled to make the necessary contributions. Prof. WILSON would have it done by establishing industrial fellowships that would earn an adequate return for the service rendered. This takes no account, however, of one phase of the subject which we have emphasized before—viz., the unfair competition between the university and private consultants who, indeed, are the university's primary product. On this score the plan is indefensible, Prof. WILSON himself naïvely admitting the advantages which the university enjoys over the man who is making his livelihood by selling technical knowledge and service. The "Tech" plan undoubtedly has merit, but in our judgment it is not the best solution of the problem.

The proposal of Messrs. HOSKINS and WILES, on the other hand, is novel and full of promise, although the authors themselves recognize certain pitfalls in its execution and the safeguards that must be thrown about

it. The personal element of administration enters strongly into the success or failure of the scheme. They believe, however, that university scientific research can best be fostered and supported by patenting the discoveries of the research staff, granting to industry non-exclusive licenses for the use of the inventions, and applying the royalties therefrom to the further support of scientific research by paying salaries commensurate with the ability demanded and reasonably comparable with those paid for industrial work of the same caliber.

Students of this plan will be struck by its similarity to the one recently proposed for handling the patentable inventions of Government employees. In both cases we find scientists engaged in public or quasi-public work, making patentable discoveries as a direct consequence or byproduct of their researches. There is a marked difference, however, when it comes to administration of the resulting inventions. In the case of the Government the work is done at public expense and the results should be freely available to all without discrimination in granting licenses. In the university, according to the present plan, the invention becomes the property of the institution and its use may be licensed with propriety, though here also the authors of the idea recognize the necessity of preventing monopoly, the chief object in licensing being to assure an income for the continuation of research. As a whole the plan represents an advance over any thus far proposed and merits consideration and a fair trial, at least until a better one is suggested.

Never Built, But Building

INDUSTRIAL plants operating in the production of materials where chemical processes are involved are ever in a state of flux as regards the layout of machinery, apparatus and buildings. New findings through both research and accidents of operation are continually showing that a rearrangement of the flow or an addition of new features will effect savings in production which more than offset the cost for reconstruction of existing plant.

The construction foreman has become a permanent member of the staff of every important chemical manufacturing institution and is usually an important one. He is continually employed in adding towers, flues and buildings, or placing new apparatus designed to improve the plant. His repairs often amount to a complete rebuilding of old units. This condition is accounted for when it is borne in mind that the industry is developing at an enormous rate and on a broadening scale and that the value of scientific control is just coming to be recognized fully by the directors of those industries in which timeworn, so-called secret methods fail to meet new technical competition.

This changing of equipment does not always call for large expenditures to effect greater savings, but changes are nevertheless essential to continued economic health. When all industry awakens to this condition common to chemical industries—namely, that a change of mind is a sign of progress, and during times of business depression with consequent strenuous competition is absolutely necessary to the existence of many concerns—the return from such periods to normal conditions can never be long delayed.

There is material for thought then in the fact that chemical plants are never built, but building.

Readers' Views and Comments

Birkeland-Eyde Arc Process of Nitrogen Fixation

To the Editor of Chemical & Metallurgical Engineering

SIR:—The Norsk Hydro-Elektrisk Kvelstofaktieselskab of Christiania, Norway, which owns the big nitrogen plants at Notodden and Rjukan, wishes to make the following statement:

It appears from the stenographic report of the "hearing before the Committee on Agriculture and Forestry, United States Senate, on S. 3,390," that the president of the American Cyanamid Co., Frank S. Washburn, has obtained a hearing before the committee and that he has taken the opportunity at this hearing to try to reduce to nothing the importance of the arc process, particularly the Birkeland-Eyde process.

We wish to state in this connection that we do not, on principle, as a rule reply to erroneous or refutable statements about the methods used by our company. We therefore do not see any reason why we should, generally speaking, take any notice of Mr. Washburn's statements whatsoever, especially as it must be clear to everyone conversant with the development of the atmospheric nitrogen industry that Mr. Washburn's version of the facts is incorrect.

We think, however, it only proper to attend to Mr. Washburn's statement concerning the utilization of the arc process in America, and which he attributes to Sam Eyde (page 174 of the hearings). We have placed this matter before Mr. Eyde, who in reply maintains that he has never expressed himself to Mr. Washburn in the manner indicated. On the contrary, Mr. Eyde states that he has been striving for years to open the eyes of the American industrial and financial interests to the great advantage the Birkeland-Eyde process would proffer to America.

We further wish to point out the following statement, made by Mr. Washburn (page 129 of the hearings):

Now there is an enormous Norwegian plant, as you know. The representative of the banking interests which own that plant has been to see me quite lately, within the last two months; he was sent over here for the purpose of consulting on what practical use that plant might have. Out of this war they amortized the plant, the full cost of the plant, which was enormous.

No representative of the banking interests of our company has had a consultation of this kind with Mr. Washburn. Therefore this statement by Mr. Washburn is untrue.

As to the rest of Mr. Washburn's statements concerning the arc process and our plants, all we care to say is that we find it quite superfluous to reply to them at all.

HARALD BJERKE,

Director General,
Norwegian Hydro-Electric Nitrogen Co.,
Christiania, Norway.

To the Editor of Chemical & Metallurgical Engineering

SIR:—In reference to the criticism made by Harald Bjerke of the Norwegian Hydro-Electric Nitrogen Co. on the testimony of Frank S. Washburn before the Senate Committee on Agriculture and Forestry with reference to S. 3,390, I think Mr. Bjerke has attached undue

emphasis to certain isolated sentences which when removed from the context could easily lead to erroneous conclusions. Thorough and careful reading of Mr. Washburn's testimony shows that not only did he appreciate the value of the arc process by at one time negotiating for its American rights, but I know that even many years later he publicly conceded its commercial value, particularly for the production of nitric acid under certain economic conditions. I am certain Mr. Washburn has in no sense attempted to discount the arc process as a fundamental proposition, but rather to show that as the arc process is at present developed it can play no important part under existing conditions and power costs in the fertilizer industry of this country.

That Mr. Washburn is correct in this analysis I think has been adequately borne out by the recommendations of the various commissions and bureaus which formulated a governmental nitrogen program. No recommendations were made in any of these reports that we install such arc process, but the conclusion does appear in them that the arc process is inapplicable to American conditions. The fact that the arc process has made no headway in this country in the nearly twenty years of its existence, although several attempts at installation have been made, further bears out Mr. Washburn's conclusions in a most effective manner.

With reference to the statement of the representative of certain foreign bankers interested in the Norwegian plant, I was present at this conference and in fact held several conferences with this French representative and take issue with Mr. Bjerke as to the truthfulness of Mr. Washburn's statement in this respect.

As a controversy over such matters of fact are trespassing upon the courtesy of the editor of such a journal as this, I should be very pleased to take up the matter personally with Mr. Bjerke or his representative and place before him names, dates and subject matter of conferences held with the individuals referred to.

New York City.

W. S. LANDIS.

Prof. Milton Whitney and Nitrogen Fixation

To the Editor of Chemical & Metallurgical Engineering

SIR:—In connection with my statement in CHEMICAL & METALLURGICAL ENGINEERING for April 6, 1921, concerning the present status and future plans of the Fixed Nitrogen Research Laboratory I wish to call your attention to the fact that prior to the foundation of this laboratory governmental research on nitrogen fixation had been in progress for a number of years under the direction of Prof. Milton Whitney, Chief of the Bureau of Soils. It was due to Prof. Whitney's far-sightedness that the potential seriousness of the nitrogen problem to America was originally appreciated by the Government. His bureau started research along this line as early as 1911, and this work has continued until the present day.

At the time when the War Department became vitally interested in nitrogen fixation from the munitions point of view Prof. Whitney and his colleagues generously co-operated with the Ordnance Department,

and this co-operation was continued after the foundation of this laboratory. At the present time a portion of the work at the Fixed Nitrogen Research Laboratory is carried out under the direction of the Bureau of Soils and by investigators carried on their payroll. It is unfortunate that no mention of this assistance was made in the recent article which appeared in *CHEMICAL & METALLURGICAL ENGINEERING* describing the work of the Fixed Nitrogen Research Laboratory. The omission was due to the fact that the article in question was taken from a report made by the Director to the War Department, which dealt only with the immediate interests of the Ordnance Department.

In the future more emphasis will be put on other methods of nitrogen fixation, and as a matter of fact for some time the laboratory has been planning work on the cyanide process.

RICHARD C. TOLMAN.

Fixed Nitrogen Research Laboratory,
Washington, D. C.

Function of Educational Institutions in Research

To the Editor of Chemical & Metallurgical Engineering

SIR:—A recent editorial in your columns (Feb. 16), entitled "The Function of Educational Institutions in Research," expressed three opinions from which there can be no reasonable dissent. These may be concisely stated as follows:

1. The primary function of the university is to educate its students.

2. University laboratories are best fitted to carry out fundamental scientific research, as distinct from industrial research.

3. There is great need for more such scientific research.

However, in drawing from these premises the conclusion that university laboratories should in general not carry on industrial research one essential point appears to have been overlooked—namely, how are funds to be obtained to carry on this desirable large amount of scientific research? Assuredly the universities in their present financial condition cannot do so to any large extent, nor are the salaries and spare time of the university professors adequate to enable them to carry on any considerable amount of such work. Theoretically, the industries themselves might well support such fundamental research at the universities, but with a few notable exceptions they have not done so.

Under the circumstances, therefore, the most promising method of securing the funds required for purely scientific investigations appears to be to *earn* them. This can readily be done by carrying on industrial research for outside companies—not on a low cost basis such as is frequently employed, which is manifestly unfair to outside commercial laboratories, but on a basis which will enable the laboratory to carry on an almost equal amount of fundamental scientific work which is to be published. In other words, the charges should be fully equivalent to those charged by high-grade commercial laboratories for industrial research; but the amount which would normally go to profits, taxes, rent, etc., in such a concern would here be devoted to the scientific research of which there is so much need.

From an *educational* standpoint, as well, this method of procedure would appear to be justified. Certainly one of the most important functions of a university or technical school is to train men for *industrial* research, and no satisfactory method of giving such train-

ing has yet been found except to have the men *do* industrial research under competent direction and with adequate library and laboratory facilities. Such a university laboratory should never endeavor to build up a large permanent staff of experienced men but rather to keep a nucleus of such men, who also do some teaching, and have the main bulk of the research handled by men who remain for one, two or three years after graduation and then go into industrial positions—frequently with the companies for which they have been working.

The presence of such work in a university laboratory also has a beneficial influence in keeping the university in close touch with recent industrial developments and suggests a large number of thesis and graduate research problems which are much more attractive to the average student than the more typical university problems—especially compared with the mere determination of physical constants, which your editorial suggests as being one of the proper functions of a university laboratory.

Several university laboratories are already operating successfully on this basis—for example, the Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology, has grown within two years to number twenty-five full-time men, and work is being carried on for about fifteen large industrial concerns. The laboratory makes it a principle not to undertake analytical or purely plant problems, but only the more fundamental type of investigation, which bids fair to continue over a considerable period, as the laboratory believes it can render its best service to industries along these lines. It frequently works in close co-operation with the research laboratories of large industrial concerns in attacking problems of major importance. Handling this industrial research has made it possible to carry on about four times as much fundamental scientific work and to train six times as many men as would otherwise have been possible. Furthermore, several of the companies for which work is done have given permission for the publication of results secured at their expense.

Some such basis of carrying on industrial research in university laboratories would therefore appear to be justified on the very premises on which your editorial based its objections.

ROBERT E. WILSON,

Research Laboratory of Applied Chemistry,
Massachusetts Institute of Technology,
Cambridge, Mass.

Director.

Practical Jokers Among Workmen

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have just read with interest the article on "Practical Jokers Among Workmen" in the April 6 number of your magazine. I am sure that everyone interested in safety work will agree with the author.

I would like to point out that in two of the cases he mentions the accidents might have been avoided if the machinery had been properly guarded, in one case where a man's arm was torn off and in another where a woman's scalp was torn loose by moving belts. Modern safety practice requires that all belts with which it is possible to come in contact be protected by adequate guards.

Carelessness can never be completely prevented and guards should always be placed around moving parts that can in any manner cause accidental injury.

HORACE F. LUNT.

State Bureau of Mines,
Denver, Col.

T.A.P.P.I. BANQUET AT THE WALDORF-ASTORIA, NEW YORK, APRIL 15, 1921

Sixth Annual Meeting of T.A.P.P.I. Held in New York

Technical Association of the Pulp and Paper Industry Holds Convention at the Waldorf-Astoria to Discuss Pulp and Paper Technology and Plant Operation Problems

DURING the week of April 11 about one-tenth of the technical personnel of the American pulp and paper industry gathered in New York to attend the meeting of their association. In the presidential address Raymond S. Hatch drew attention to foreign appreciation of the value of T. A. P. P. I. by the institution of similar organizations both in Great Britain and France. President-elect George E. Williamson reported that rapid progress was being made in the preparation and publication of the series of textbooks on "The Manufacture of Pulp and Paper." Vols. I and II, dealing with the preliminary sciences, are now available and Vol. III, on the manufacture of pulp, will appear this fall.

The activities of the association are directed by fifteen committees. Reports and addresses on technical topics pass through them to Secretary Thomas J. Keenan, who publishes them in the *Technical Association Papers*. As limitations as to space require that only brief notes on the major topics be made here, the reader wishing more elaborate details is directed to the extensive report of the meeting in the April 14 issue of the *Paper Trade Journal*, pp. 189-263 and 335-339.

NEW HALL PROCESS OF GRINDING WOOD

A 50 per cent saving in sulphite pulp beater furnish is claimed in paper mills using the Hall process ground wood pulp. The surface of the stone is burred, giving grooves through which the fiber can escape before being reduced to wood flour. About 250 lb. of pulp per cord is gained at the same time. Experiments at the St.

Regis Paper Co. have been under way since 1914. Steam cooking has been found advantageous both in softening the wood and in giving a sterile pulp.

EFFECT OF VARIABLES ON BLEACHING EFFICIENCY

Bleaching powder was shown to give best results at temperatures up to 120 deg. F., with stock consistency around 7 per cent. Variations of around 40 per cent in bleach were obtained with lower temperature concentrations of pulp, using 10 lb. of powder per 100 of pulp. This is actually a function of bleach concentration and should be further studied with variations in acidity in bleaches made direct with chlorine and bases other than lime.

EVALUATION OF LIME BY CAUSTICIZING TEST

Some time ago Martin L. Griffin suggested that the soda ash value should be taken on the lime supplies to determine the causticity. As is well known, lime burned and sintered in an electric furnace is inert even to hydrochloric acid, and even kiln-burned lime can be dead-burned to a greater or less degree according to the magnesia and other flux content. Tests on lime with 93 per cent CaO were submitted, showing 86 per cent soda ash conversion, and limes with as low as 63 per cent conversion were mentioned, the equilibrium being a function of reaction time.

SHORTENING SULPHITE DIGESTION

The Forest Products Laboratory has recently run semi-commercial trials of forcing sulphite liquor into

the charge by preliminary air pressure. Rapid penetration was obtained so that digestion temperatures could be applied much sooner, with considerable saving in time. The combined SO_2 used was too low to give results that should be had with normal operation. High-pressure digestion is undoubtedly going to come more and more into practice and be limited only by safety considerations.

A STUDY OF CASEIN

The committee on coated paper gave a set of specifications and tests on casein, which should be free from lumps when dissolved in an alkaline soda salt such as borax or carbonate, be in a sterile condition free from mold or decomposition products, and bond china clay in a 6 to 7 per cent mixture to furnish the required coating adherence. Tests for solubility, strength, moisture, color, odor, acidity, insoluble matter, ash, alkali, starch, viscosity and grease were described.

SULPHITE COMMITTEE DISCUSSES SUPERHEATED STEAM

The discussion by the sulphite committee centered on the use of superheated steam. Trials in the past indicate that there are chemical advantages which are more or less offset by mechanical difficulties in the boiler house and steam delivery system. Insulation of digesters is being tried out in a few plants, and while no leaks have yet been reported, it is felt that no difficulty will be found in catching them. Partial insulation leaving the base exposed was not thought to be desirable, due to the temperature strain that would be induced, though one plant is trying it out.

LONGWORTH BILL INDORSED

The committee on dyestuffs reported that diminishing trouble was being experienced with paper colors and reported a resolution indorsing the Longworth bill which was voted upon and passed in the assembly.

BIBLIOGRAPHY

The committee on bibliography is preparing a reading list on sulphate pulp, marbled papers, dyeing of pulp, drying of paper, cigarette papers, analytical procedures and paper textiles. About twenty-five lists have been submitted in the past making all published facts available without effort in library search. Clarence J. West, chairman of the committee, is now located with the National Research Council at Washington and will be glad to receive and reply to any inquiries regarding bibliographies on pulp and paper subjects.

WATERWHEEL EFFICIENCIES

Prof. Charles M. Allen of Worcester Polytechnic Institute described the use of the Alden dynamometer in the water-power-driven ground wood pulp mill. He spoke of bad practice and cataloged case after case where poor efficiencies were being obtained on down to where the water turbine was in circuit with steam and actually being driven as a pump—consuming power instead of delivering it. All water-power equipment should be frequently tested to be maintained in an efficient condition.

USE OF WASTE HEAT IN VENTILATION

The Briner economizer and heat exchanger counter-currents the hot exhaust air from the paper rollers to the incoming supply, thus affording dry air from the

outside at any required temperature. A steam radiator is in circuit for use when sufficient heat is not obtainable from the exhaust due to shutdowns and interruptions in operation. A cold air shunt is also installed to make temperature regulation possible.

THE ALLEN WEIGHTOMETER

The Allen weightometer was described by E. J. Trimbe and is designed to weigh and record continuously anything from chips to liquor. Six triangular open pockets set in the form of a hexagon drum revolve in such a way that a set load releases each when filled and automatically unloads and records each filling during the revolution.

PAPER MOISTURE CONTENT INDICATOR

Dr. C. B. Thwing demonstrated a beam balance designed to show moisture percentage direct without calculation. The accuracy of the instrument depends on the constancy in the weight of stock which is calibrated against a dried gage piece. As the bond in paper is influenced in strength and other physical properties by the moisture content, it is essential that the moisture content should be tested in conjunction with these other tests.

NEW SULPHUR PLANT DESCRIBED

The Bureau of Mines moving picture of the Texas Gulf Sulphur plant at Matagorda, Tex., visualized the process by which this important raw material is mined in quantities sufficient to supply the markets of the entire world. The liquid sulphur is pumped for miles in steam-jacketed lines, stored in 170,000-ton vats and shipped from the port of Galveston, which is near by. The record capacity of this plant is reported as 2,500 tons per day of commercially pure brimstone averaging 99½ per cent sulphur. The purity is probably due to the gypsum source, which is free from selenium and arsenic.

BANQUET

Tuesday night was set aside for the annual feast at the Astor, which was so attractive that we are publishing the photograph by way of ornament. Judge Charles F. Moore was toastmaster and introduced each speaker with a little prelude tale. We are commenting editorially on the principal talk of the evening by Prof. Marston T. Bogert. Ellwood Hendrick aroused the greatest amusement with his chemistry and psychology of odor and smell. Philip T. Dodge presented his views on what degree of finish the raw recruit from the technical schools should have to be welcome in the mills of the International Paper Co. Mr. Dodge desires that paper technology and manufacturing practice be taught to the student, and of course this can be and is carried out after a fashion in a few technical schools, but the big question is: Has the manufacturer any right to push all the burdens of such education on to the schools? We would like to present the views of the technical men at the round tables, but think it enough to state that very few agreed with the speaker.

FALL MEETING

The next meeting will be held in September in Washington, where the Bureau of Standards and Government printing plants will be inspected. An excursion will be made to the plants in the Wilmington and Philadelphia districts at the conclusion of the meeting.

Residual Aluminum Compounds in Water Filter Effluents

Theoretical Considerations Indicating the Influence of the Hydrogen Ion Concentration on the Solubility of Aluminum Hydroxide—Various Conceptions of Aluminum Sulphate Reactions With Natural Alkaline Waters

BY ABEL WOLMAN* AND FRANK HANNAN†

ALUMINUM sulphate as a coagulant has been employed for such a long term of years in our water supplies that it would appear to be unnecessary to discuss at this late date any of the peculiarities of its reactions. That such discussion is desirable, however, is clear, when we view in retrospect the development of certain concepts of chemical transformations. As the fields of chemistry and physics become better explored there gradually appears a realization of the continual energy of reactions. The assumptions of rigidity and irreversibility of the interactions of substances need to be abandoned. With such assumptions, it becomes necessary also to discard some of the "fundamental truths" which no longer appear either "fundamental" or "true."

In a number of respects, orthodox conceptions of the action of alum in water seem to require some modification and extension. Such changes in viewpoint may be particularly desirable at this time, when discussion in waterworks fields has again reverted to the problem of residual alumina in filter effluents. For this reason the writers considered it a fruitful task to attempt in this paper to develop as briefly though as accurately as possible an understanding of the mode of action of alum as a coagulant. In such a development the causes of certain associated phenomena, such as disappearance of flock, positive reaction for alumina in filter effluents and imperfect coagulation with low alkalinity, may also appear. For purposes of clarity it is well to point out that in the discussion to follow we are not concerned with the passage, through filters, of undecomposed aluminum sulphate due to insufficient alkalinity or of flocculated hydrate through breaks in filter beds. In other words, our discussion refers to difficulties inherent in natural processes and not to those resulting from unintelligent application of chemicals or operation.

In order to provide for an orderly presentation of the subject, the writers have decided to devote this paper to theoretical considerations, with only such additional data as will be necessary to clarify some of the ideas presented. The experimental proof of some of the hypotheses here set forth is still lacking. One of the important purposes of this discussion is to call forth a greater amount of experimental work in this field than has so far been accomplished. A number of the facts should be tested out in routine practice, so that large-scale findings may substantiate or refute laboratory suggestions emanating from this and other fields. If such a program were carried out, the various phases of the alum problem might be satisfactorily solved. These phases include: (a) theoretical considerations, (b) experimental data, (c) conclusions, (d) significance of results (sanitary, physiological, etc.). Our contribution,

as we have stated before, is to be restricted to (a)—theoretical considerations. Perhaps in the course of time the supporting material for (b), (c) and (d) will be forthcoming.

ALUMINUM SULPHATE REACTION—USUAL CONCEPTION

The simplest and most popular conception of the reaction of aluminum sulphate with the natural alkalinity of water is given by the following typical equation:

This rigid transformation is usually accepted as approaching the average state of affairs when "normal" conditions obtain. The above equation has been responsible for the oft-repeated statement that "if sufficient raw water alkalinity is present, there is no excuse for the passage of aluminum compounds through filter beds." The simplicity of the reaction has been so frequently emphasized that the impression has been gained by the average filter plant operator that when the coagulum, $\text{Al}(\text{OH})_3$, is not instantly and continually formed, the treatment is either careless or faulty. When inquiry, however, among many operators elicits the information that such difficulty as ineffective flock formation and residual alumina in filter effluents are by no means rare occurrences even with plenty of alkalinity, it seems wise to search for causes in other places than poor operation.

Such a search demands at once a reconsideration of alum reactions. Since the study of such reactions has been retarded in the waterworks field by the general hesitancy to question orthodox beliefs, it is necessary to pursue our inquiry into other channels. When this is done, two important series of data appear. These series are in conflict as to the nature of the compounds resulting from alum reactions, but are in complete agreement as to the absence of rigidity of state of any particular aluminum compound. In other words, we must pass from a viewpoint in which alum reactions result in stationary phenomena to one in which they appear as mobile, delicate equilibria. With such a new viewpoint, the formation of an insoluble coagulum as $\text{Al}(\text{OH})_3$, when aluminum sulphate is added to water, becomes a desirability, but not necessarily an eventuality. Our problem now becomes to determine those factors which regulate the reaction in such manner that the desired result, an insoluble complete coagulum of $\text{Al}(\text{OH})_3$, is obtainable.

RECENT INTERPRETATIONS BASED ON HYDROGEN ION CONCENTRATION

The important characteristic of recent conceptions of $\text{Al}_2(\text{SO}_4)_3$ reactions is to be found in the realization

* Maryland State Department of Health, Baltimore, Md.
† Toronto Water Filtration Plant, Toronto, Canada.

that the formation of $\text{Al}(\text{OH})_3$ is a reversible progressive reaction, dependent upon a number of conditions, the most important of which is probably the hydrogen ion concentration or p_H value of the solution in which one is working. The nature of the solutions obtained, however, when aluminum hydroxide is dissolved in the presence of acids or bases has been the subject of much discussion. The underlying hypotheses of these discussions may be divided into two classes. In the first case, the solution of $\text{Al}(\text{OH})_3$ is ascribed to processes of peptization or change in physical structure of $\text{Al}(\text{OH})_3$, but not to change in chemical composition. The second school of thought bases its understanding of the processes entirely upon the hypothesis that the changes taking place when $\text{Al}(\text{OH})_3$ is formed and redissolved are due to variations in chemical combination. The contrasting viewpoints emphasize changes in physical state as against changes in chemical combination. The salient features of each conception are outlined at some length below, in order to demonstrate that, whatever viewpoint is accepted, one must reach the conclusion that the complete formation of the insoluble $\text{Al}(\text{OH})_3$ in water is by no means as frequent an accomplishment as has been tacitly assumed.

CHANGES IN PHYSICAL STATE

The evidence supporting the hypothesis that $\text{Al}(\text{OH})_3$ may be redissolved in solutions through the increase of hydroxyl ions, because of a process of peptization or subdivision of particles, is by no means complete. Mahin, Ingraham, and Stewart,¹ for example, conclude that aluminum hydroxide should not be considered as amphoteric since they claim to have established by the measurements of the heat of solution of aluminum hydroxide in sodium hydroxide, of the quantitative relations between ammonium nitrate and sodium aluminate and observations made upon the electrolysis of sodium aluminate that the colloidal properties of aluminum hydroxide play a far more important part in conditioning its solubility in bases and acids than the possible formation of aluminates. In addition, Chatterji and Dhar² state:

"In the case of the action between sodium hydroxide and the hydroxide of copper, chromium, lead, zinc, aluminum and mercury, the following results are obtained. The conductivity of a solution of caustic soda did not appreciably change on the addition of hydroxide of chromium, aluminum, lead and mercury, while in the case of zinc the resistance of the caustic alkali solution appreciably increased when zinc hydroxide was dissolved in it. Hence we can conclude that the solutions of aluminum hydroxide, chromium hydroxide, lead hydroxide, mercury hydroxide and copper hydroxide are cases of true peptization and not of chemical combination. On the other hand, in the case of zinc hydroxide, we get more of chemical combination than of peptization. Or, in other words, the major part of the hydroxides of Al, Cr, Cu, Pb, Hg exists in sodium hydroxide solution as a colloid, while the major part of zinc hydroxide remains as a zincate. . . . Similarly the hydroxides of Al, Fe and Cr form colloidal solutions in acetic acid, while zinc hydroxide forms zinc acetate."

The above statements give a fair representation, it is believed, of the hypotheses presented by the adherents of the "peptization" theory. It is important to emphasize that these authors and others have demonstrated the ephemeral character of the insoluble $\text{Al}(\text{OH})_3$. They

support simply one explanation of the cause of the solution and precipitation of the hydroxide—namely, that due to change in physical structure because of some effect of hydroxyl ions. They disagree with the second class of workers, not on the fundamental idea of the instability of the insoluble $\text{Al}(\text{OH})_3$, but only on an explanation of the cause of this instability.

CHANGES IN CHEMICAL CONSTITUTION

The basis of the explanation of the change of state of $\text{Al}(\text{OH})_3$ as due to a change in chemical constitution may best be indicated by the following quotation from Stieglitz:³

"Aluminum hydroxide dissolves in acids. From its solution in hydrochloric acid, an aluminum salt, aluminum chloride, $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$, is obtained. It also combines with strong bases, dissolving, for instance, in a solution of sodium hydroxide and forming an aluminate, NaAlO_2 According to the best knowledge we have on the subject, the molecule of aluminum hydroxide has the following structure or arrangement of its atoms $\text{Al}(-\text{O}-\text{H})_3$. It is readily seen that the cleavage of the molecules may produce either aluminum and hydroxide ions, characteristic ions of a base, or aluminate and hydrogen ions, characteristic ions of an acid:

Loeb⁴ further adds that "it is obvious that between the action of acids and of bases producing these two types of electrolytic dissociation there must be one hydrogen ion concentration in which aluminum hydroxide is practically neither able to form Al^{+++} nor AlO_2^- ions, and this would be the isoelectric point. The significance of this statement will appear later in the discussion.

Wolfgang Pauli⁵ recently strengthens this conception by concluding, as a result of an exhaustive physico-chemical analysis, that the aluminum hydroxide sols may be considered as complex salts of the composition:

where An is the anion of the salt used in preparing the sol.

The question naturally arises now as to what conditions determine the formation of the insoluble hydroxide and the soluble complex salts of aluminum. In the answer to this question should appear the clue to the cause of the puzzling features of present-day coagulation problems in water supply. Fortunately an abundance of experimental data are available in different fields. They are of sufficient interest and value to discuss at length in this paper. Their practical importance in indicating a solution of our specific problems will be outlined in a later section of this discussion.

In March, 1913, at the Milwaukee meeting of the American Chemical Society Hildebrand⁶ presented a paper on "Some Applications of the Hydrogen Electrode in Analysis, Research and Teaching." In this paper Hildebrand demonstrated definitely that aluminum hydroxide is precipitated by sodium hydroxide, while the solution of aluminum sulphate is still strongly acid, the hydrogen ion concentration during the precipitation varying roughly between 10^{-3} and 10^{-5} . He also shows that aluminum hydroxide goes into solution with an excess of alkali, in which the proportion of alkali used corresponds to the formation of $\text{NaAlO}_2 - n\text{H}_2\text{O}$. It is interesting to recall that Hildebrand supported the theory of the solution of aluminum hydroxide as an

acid rather than as a colloid, as claimed by Mahin, Ingraham and Stewart.¹ Hildebrand bases his refutation of the above authors' contention upon the fact that the ultramicroscope fails to show the presence of a colloid in the solutions studied, although the ordinary solutions of aluminum hydroxide produced by dialysis show submicrons very plainly in the ultramicroscope. The conclusions reached by Hildebrand were later substantiated by Bancroft⁷, Blum⁸, Pauli⁵ and others.

The work of Blum⁸ is most significant in attempting to clarify some of the results frequently obtained in the application of aluminum sulphate to water. This author has made extensive studies of the reactions of the aluminum compounds with certain bases. His studies are interesting and valuable. From his experiments on the action of sodium hydroxide upon AlCl_3 he notes that precipitation of $\text{Al}(\text{OH})_3$ begins when p_H is about 3 and is complete before p_H is 7. He finds that for the transition state from p_H 7 to p_H 10.5 a dissolving of aluminum hydroxide in sodium hydroxide is progressively in action, until at the latter point the solution is almost entirely clear. The constitution of the compound contained in the solution at this latter point is indicated by Blum, but the details of this particular subject need not concern us at this time.

The results of Blum's experiments appear to indicate the existence of definite aluminates of the formulas NaAlO_2 and KAlO_2 (or multiples thereof) in solutions obtained by the action of alkalis upon aluminum hydroxide. More importantly for the particular subject with which we are now concerned, the experiments demonstrate beautifully that the amount of $\text{Al}(\text{OH})_3$ held in a given alkaline solution is a function of the alkalinity of the solution. This conclusion cannot be too greatly

between 6.5 and 7.5. What is this point of optimum precipitation in our different water supplies? Have we ever paid any attention to it? We must expect certainly that there are numerous points in coagulation in which re-resolution of $\text{Al}(\text{OH})_3$ is always in operation. The occurrence of aluminum compounds in filter effluents should be as common as it is now considered rare. Chance, and not mischance, in the past seems to account for its failure to appear.

Further important experimental work on the reactions and constitution of aluminum compounds may be found in the studies by Heyrovsky⁹ on the electro-affinity of aluminum, by Michaelis,¹⁰ and on the production and chemistry of satin whites by Cobenzl.¹¹ The latter adduces reasons for his belief that the reaction of $\text{Al}_2(\text{SO}_4)_3$ with $\text{Ca}(\text{OH})_2$ is as follows:

It is interesting to note that Cobenzl suggests that

TABLE I (ADAPTED FROM BLUM)
Precipitation of $\text{Al}(\text{OH})_3$ by NH_4OH at Various Hydrogen Ion Concentrations

Exp. No.	Approximate p_H	NH_4Cl Added g.	Al_2O_3 in Filtrate g.	Remarks
1	6.0	5	0.0010	
2	6.0	5	0.0012	
3	6.5	0	Appreciable	Coagulated poorly

10	9.0	5	0.0004	

NOTE.—Table I shows that considerable aluminum hydroxide remains unprecipitated at p_H values, varying much from 6.5 to 7.5, as shown by filtrate readings in experiments 1, 2, 3, 8, 9, 10.

FIG. 1. EFFECTS OF H ION CONC. ON SOLUBILITY OF $\text{Al}(\text{OH})_3$. (AFTER BLUM)

stressed, since it appears to the writers of this paper to be the basis of a new and better understanding of the whole mechanism of alum coagulation.

The obvious resultant of the above tests is stated in brief by Blum:⁸

"In the case of amphoteric hydroxides, such as $\text{Al}(\text{OH})_3$, it is obvious that an excess of the base is to be avoided and it therefore becomes desirable to select that degree of alkalinity which will insure most nearly complete precipitation and at the same time avoid resolution of the precipitate." (The italics are ours.)

In Table I are shown certain data adapted from one of Blum's publications which show quantitatively that the precipitation of aluminum hydroxide by ammonium hydroxide is complete when the p_H of the solution is

calcium aluminate, when formed, is in a colloidal state, and the particle size may be regulated by the degree of alkalinity of the solution. May we not find it necessary to search for such complex configurations in our water supply reactions before scientific control is possible?

By way of digression, it is well to call attention at this point to the difference between "precipitation" and "sedimentation" concepts. It is possible to conceive that the points of optimum precipitation and of sedimentation need not coincide. As a matter of fact, there is considerable evidence to suggest that these points rarely coincide. Blum,⁸ for example, defines "precipitation" as the chemical formation of $\text{Al}(\text{OH})_3$. "This compound (especially in the absence of salts) may not actually coagulate or form a visible precipitate until from one-third to one-half of the alkali required for complete precipitation has been added. The point at which a visible precipitate occurred in the different experiments was found to be very variable." Likewise, Mukhopadhyaya,¹² working on the coagulation of arsenious sulphide sol by electrolytes, finds that settling or sedimentation plays an extremely small part in the coagulation of colloidal arsenious sulphide.

The subject of the effect of the hydrogen ion concentration upon the physical state of such amphoteric colloids as $\text{Al}(\text{OH})_3$ should not be left without making somewhat complete reference to the great amount of excellent work performed upon organic compounds of similar structure by Loeb.⁴ We can find no better method of clarifying the concepts we have attempted to present in this paper than by quoting at length from one of Loeb's papers dealing with analogies between solutions of gelatine and aluminum salts.

"Gelatine is an amphoteric electrolyte which when the hydrogen ion concentration of its solution exceeds the critical value $2 \times 10^{-5} N$ forms only salts of the type of gelatine chloride, gelatine sulphate, etc., while when its hydrogen ion concentration falls below this value it can form only salts of the form of metal gelatinates—e.g., Na gelatinate, Ca gelatinate, and so on. At the critical hydrogen ion concentration $2 \times 10^{-5} N$ —the isoelectric point for gelatine—it can exist only in the form of pure—i.e., non-ionogenic—gelatine. In this condition gelatine is practically insoluble, practically non-ionized, and is practically incapable of producing any osmotic pressure. Both types of gelatine salts, metal gelatinates as well as gelatine chloride, etc., are very soluble, are strongly ionized, and are capable of producing osmotic pressure. The writer's experiments, which are not yet all published, have shown that for each given hydrogen ion concentration there exists a definite equilibrium between non-ionogenic gelatine, gelatine salts and free acid. If we have 1 per cent solutions of isoelectric gelatine, the ionized or salt portion of the gelatine is practically zero. When we add increasing quantities of an acid—e.g., HCl—an increasing portion of the gelatine is transformed into gelatine chloride, while the portion of non-ionogenic gelatine is correspondingly diminished. The relative proportion of gelatine salt and non-ionogenic gelatine depends therefore upon the hydrogen ion concentration of the solution and increases in a characteristic way with this concentration. This hydrogen ion concentration of the solution is, of course, not identical with the concentration of the acid added to the solution, since part of this acid is in combination with the gelatine forming the gelatine salt. Since practically only that fraction of the 1 per cent gelatine solution which is transformed into a gelatine salt produces an osmotic pressure, it is obvious that the osmotic pressure of a 1 per cent solution of gelatine must change in a definite way with the hydrogen ion concentration of the solution. If we use different acids we find that different quantities of acid are required to bring a 1 per cent gelatine solution to the same p_H .

"When the hydrogen ion concentration is below the critical value 2×10^{-5} (or to use Sørensen's logarithmic symbol, when $p_H < 4.7$) a part of the non-ionogenic gelatine is transformed into metal gelatinate, and this part is the greater the more the hydrogen ion concentration falls below 2×10^{-5} . This is again a definite equilibrium between hydrogen ion concentration, gelatine salt and non-ionogenic gelatine.

FIG. 2.
Chemical influence of
H Ion concentration
(after Loeb)*

*"Amphoteric Colloids," by Jacques Loeb, *Journal of General Physiology*, No. 1, Sept. 20, 1918.

Curves of the conductivity (A), osmotic pressure (B), swelling (C), and alcohol number (D) of gelatine previously treated with various concentrations of HCl.

In the region of the isoelectric point ($p_H = 4.7$) all the curves have a minimum. On the left of this point gelatine exists in the form of gelatine chloride (with high ionization), the curves rising more rapidly than on the right of the isoelectric point where the gelatine exists in the form of common gelatine which dissociates as a very weak acid.

Ordinates in curves

A—Conductivity 10,000 ohms.

B—Osmotic pressure

C—Total swelling

D—Alcohol number

"It is perhaps not without interest that the behavior of gelatine is paralleled by the behavior of amphoteric electrolytes of a crystalloid character—e.g., aluminum salts. Thus aluminum chloride exists only when the hydrogen ion concentration exceeds a certain critical value which seems to lie near that of the point of neutrality. When the solution becomes alkaline, metal aluminates are formed. Na aluminate as well as $AlCl_3$ is very soluble. At the isoelectric point neither salt can exist and the insoluble $Al(OH)_3$ is formed. The insoluble $Al(OH)_3$ has no osmotic pressure (or does not attract water) while solutions of both $AlCl_3$ as well as $NaAlO_2$ attract water powerfully. In the presence of $AlCl_3$ water molecules are apparently negatively electrified and in the presence of $NaAlO_2$ water shows positive electrification. The turning point for the sense of migration of water molecules seems to lie near or at the isoelectric point of aluminum—namely, p_H about 7.0. It would be very important if we could measure the permanent osmotic pressure of aluminum salts in collodion bags, but this is impossible since aluminum salts, with the exception of the insoluble $Al(OH)_3$, diffuse through collodion membranes. It is, however, possible to determine the influence of different aluminum salts upon the rate of diffusion of water through a collodion membrane and it is found that this influence obeys the two rules."

Material of a similar nature to the above, although by no means as extensive, has been accumulated by Patten and Johnson,¹³ Eckweiller, Noyes and Falk,^{13a} and Coulter.^{13b} Their results are confirmatory of those already presented.

SIGNIFICANCE OF PRESENT DISCUSSION IN REFERENCE TO PROBLEM OF ALUM COAGULATION IN WATER SUPPLIES

A survey of the facts and theories collected in the preceding portions of this paper has led the writers to formulate a hypothesis regarding the action of aluminum sulphate in water supplies which may properly paraphrase Loeb's conclusions as to proteins. The important features of this hypothesis are as follows:

Aluminum compounds may exist in three states, defined by their hydrogen ion concentration—namely, (a) as non-ionogenic or isoelectric $Al(OH)_3$, (b) metal aluminate (e.g., Na or Ca aluminate) and (c) alumino-acid salts (e.g., aluminum chloride, aluminum sulphate, etc.). Thus, in practically every water treated with alum, at any point other than the isoelectric point (which has not yet been determined for varying waters), an equilibrium may exist between hydrogen ions, metal aluminates and non-ionogenic or isoelectric $Al(OH)_3$. (If the p_H were lower than the isoelectric the Al ion would replace the aluminate. In water practice, however, such cases would be rare.) It is reasonable to suppose that just as often as not the p_H of a water is not correct to permit the complete formation of only $Al(OH)_3$. For this reason the occurrence of other aluminum compounds should not surprise one in filter effluents, for such compounds are soluble and need not be removed by the sand.

Some waterworks investigators have recognized the possibility of formation of aluminum compounds other than the insoluble hydroxide. In most instances, however, these possibilities have been ascribed both to insufficient alkalinity and to peptization. (Stein,¹⁴ Whipple.¹⁵) In this manner advantage has been taken of both the theories of peptization and of chemical combination. It appears from the preceding material that the

latter explanation alone may suffice if we do not neglect the important factor of the hydrogen ion concentration of the medium with which we are at work. At this point also it is important to suggest that *not only low alkalinity may be fraught with danger but too high hydroxyl ion concentration may not be so desirable* for proper and successful coagulation and for the complete elimination of soluble aluminum compounds. It seems, as a preliminary theory, that as one departs from the point or area of favorable hydrogen ion concentration in coagulation processes, one passes, in either alkaline or acid direction, into fields of re-solution of aluminum hydroxide. This conception, it is clear, is independent of the causes of such re-solution. It is important, therefore, to keep in mind the ever-present possibility of missing the favorable threshold area of coagulation and passing into the unfavorable dissolution areas. This interpretation of the action of aluminum sulphate is widely different from that hitherto accepted, in which the presence of delimited areas of effective flock formation was but little emphasized.

Does the literature of water purification disclose any data in confirmation of the above hypothesis of equilibrium conditions of alum reactions? It should be difficult to obtain such material, since it is only recently that

TABLE II (ADAPTED FROM MORISON)

Volumetric Estimation of Alum in "Solution" in Waters Treated With Various Doses of Aluminum Sulphate

* Also optimum clarification dose.

determinations of hydrogen ion concentration have been made in water. Hitherto only potential alkalinity and acidity have been determined, because of current methods of titration, while actual alkalinity or pH values have remained unknown. It is these latter conditions which are usually operative in conditioning our water supply reactions.

ZONES OF COAGULATION

Fortunately we have available an excellent series of experiments in water which does much to substantiate at least some of the possibilities of the suggestions outlined above. It is interesting to find that the author of these experiments, in the distant land of India, did not completely recognize the significance of the data which he reports. In April, 1916, Captain J. Morison¹⁰ of the Indian Medical Service reported upon a series of studies of the clarification of the water supply of Poona by means of alum. The results he obtained may be well interpreted in the light of the theoretical considerations previously presented. Morison's first experiments were made by adding increasing quantities of aluminum sulphate to the turbid water to be studied. He found that the clarification of the water with these different doses exhibited the familiar "zone phenomenon"—that is, "by increasing the dose of alum up to a certain point the clarification improves up to an optimum point where the settlement is excellent; any alum in excess of the optimum point again results in incomplete settlement. Increasing the doses of alum now gives less and less settlement, until a point is reached where the settlement

is no better than that of the untreated water. Further increments of alum produce settlement which finally becomes complete. The improvement, however, is not uniformly continuous. It is broken by waves of which as many as three have been noted." (Fig. 3.)

MORISON'S COLOR TEST

Morison,¹⁰ in addition, makes the important notation that "using now pure hæmatoxylin (Grübler) in a 1 in 1,000 watery solution . . . it was found that a red color was given by the natural water and by the water completely clarified by a dose of alum just sufficient to clear it. If this dose were not attained the water was turbid and gave a lavender or purple color with hæmatoxylin. If the dose were exceeded the clear solution gave either a reddish color which was rapidly decolorized, or a permanent bluish lavender; the latter color appearing when the dose of alum approximated or exceeded 2.2 times the alkalinity. This seemed a curious result. The hæmatoxylin, used to detect the presence of alum, showed that the alum was completely pre-

FIG. 3. CLARIFYING EFFECTS OF ALUM (AFTER MORISON)*

cipitated at a point corresponding to half the weight of alum necessary to react completely with the alkalinity of the water, and that both below and above this point, *in spite of there being in each case an excess of available alkali, there still remained some alum in solution.*" (Present authors' italics.)

Morison then concludes: "In the above experiments where the aluminum sulphate was present in quantities in which it ought to have been completely precipitated by the alkalinity of the water, certain of the aluminum hydrate remained in the supernatant fluid except when the optimum dose of alum was used." With this conclusion in mind, Morison then determined quantitatively the amount of alum present in such supernatant liquors and found that alum could always be detected when the doses were below the optimum point. At the optimum dose the alum, if present at all, was in minute quantities. Morison's figures are given in Table II. It is interesting to recall also that Morison found residual alum present in slow sand filter effluents in Poona, where alum-treated waters were being applied to slow

*"The Dose of Alum for the Clarification of Water by Precipitation," by Captain J. Morison, *Indian Jour. Med. Research*, vol. 3, No. 4, April, 1916.

sand beds. The results were not surprising. The converse of this has been observed by one of us, when on one occasion the alum application was eliminated completely from a mechanical filter for five consecutive days. The effluent nevertheless continued to give the alumina reaction with little or no reduction during the whole of this time.

Of even greater significance in connection with the present subject is the fact that Morison demonstrated that the hæmatoxylin test reacted with hard waters (356 p.p.m.) in a manner very similar to that described for the soft waters (25 to 50 p.p.m.). "Below the zone of settlement, hæmatoxylin gave a gradation of shades of lavender; at the optimum point a red color was produced; immediately above this point the hæmatoxylin was decolorized and, when the dose exceeded 610 p.p.m. (alum) the lavender color returned."¹⁶

IMPORTANCE OF p_H

A close study of Morison's curves and figures leads one at once to the conclusion that the phenomena he noted were entirely due to changes in hydrogen ion concentration, similar to those outlined in the earlier portions of this paper. The similarity between Morison's curves and those recently presented by Smith¹⁷ is so striking as to lend further emphasis to the controlling importance of p_H in determining coagulation phenomena. Morison¹⁶ was groping for this explanation when he suggested: "It would seem as if the precipitation of the colloids were not so much due to the neutralizing of the charge on one sol by that of another sol or by an electrolyte as to a certain balancing of the acid and basic ions in the solvent, which, when balanced, and possibly by a catalytic action, bring about the coagulation and the precipitation of the colloids." It is also of great interest to recall that not long after this statement Longley,¹⁸ in discussing the nature of color in water, says: "The removal of color by means of aluminum sulphate is influenced by the amount of alkalinity in the water. For a given water there is an alkalinity comparatively low and not many points above the neutral point where the coagulation seems to be best." Does not the work of Loeb, Blum, Morison and others supply us with the quantitative evidence for the general truth of these speculations? Although the present writers are unwilling as yet to subscribe fully to Morison's statement that the optimum dose, the so-called isoelectric point, has been shown in these experiments to be independent of the amount or the nature of the colloid present, yet there is sufficient accuracy of statement therein to warrant a complete change of viewpoint regarding coagulation processes. It will probably be found that the relationships are much more complex, as has been indicated by the work of Smith¹⁷ and of Raju.¹⁹

In the waterworks field Morison¹⁶ has supplied sufficient evidence of the probable existence of a point or zone of most effective coagulation. In the case of the water with which he was working this point coincided with the point of most satisfactory sedimentation. This coincidence, we believe, was largely a matter of chance, for it is our feeling that the zone of complete coagulation is determined by p_H conditions, while that of sedimentation will probably be dependent upon many other factors. Some slight experimental evidence for this belief is given below. Much more work remains to be done, however, before any real conclusions upon any portion of this interesting subject are to appear.

If the assumptions given above are in any way war-

ranted, we should be able to test their accuracy in the following manner: Theoretically the isoelectric point for $Al(OH)_3$ should be in the neighborhood of p_H 7.0. If we are experimenting, therefore, with a water having a p_H value of 8.0 to 8.6, we should be able to obtain better precipitation of $Al(OH)_3$ if we *acidify* such a water to bring it to a value nearer p_H 7.0. The heroic treatment of acidifying a water to improve coagulation is, of course, contrary to most canons of water purification. Let us see, however, what such treatment calls forth. The data presented are very meager, but they are at the same time interesting. The preliminary experiments are described below (experiments performed by Hannan):

PRELIMINARY EXPERIMENTS—ACIDIFICATION OF WATER

Dec. 15, 1920—Water used in this experiment obtained from slow sand filter effluent, untreated with alum, alkalinity (titratable) in the neighborhood of 90 p.p.m., p_H usually varies between 8.0 and 8.6.

Two samples of 1 liter each were taken of slow sand filtered water; added to each alum at rate of "1 grain per imperial gallon," the rate used in the mechanical filtration plant. To one of the above samples was added 0.8 c.c. normal sulphuric acid. At first the addition of acid had possibly a slightly clarifying effect, but after one hour had elapsed the acid-treated water was distinctly the more opaque. It preserved its lead in this respect up to 2½ hours, when 50 c.c. of each sample was filtered through a single thickness of Whatman No. 1 paper. On adding a drop of hæmatoxylin to each, the acid-treated was brown (probably with a little less acid it would have been the usual rose tint) at first, changing to a clear yellow with one or two drops of N/6 acetic acid. The other showed the usual alumina blue changing to brown with acetic acid; it also filtered more slowly. The alkalinity of the water was somewhat more than half used up between alum and acid. One could probably work with less acid. The required p_H seemed to be around 7.3. It is easy to see why this fact has escaped observation for so long a time. We have always been told that deficiency of alkalinity is the thing to be avoided. No one would be likely to try adding acid.

In the above samples, after standing twenty-four hours in tall cylinders with atmospheric exchange through cotton wool plugs, the acid-alum sample had not begun to settle, while the alum-only had flocked and settled. On filtration through single filter paper the acid alum was still quite alumina-free, while the other showed the usual blue with hæmatoxylin. Owing to loss of carbonic acid the p_H had moved up somewhat. The waters were transferred to glass-stoppered bottles. After forty-eight hours both samples had settled clear. Acid-alum sample still quite alumina-free, while the other as usual showed the blue.

Whether acid or alum is added, it is clear that the carbonic acid liberated determines the p_H . An essentially unstable system is thereby established. It is not surprising, therefore, that in the past contradictory results have been obtained, especially when the attempt is made to correlate with the original alkalinity and the alum dosage. The reader may gain a considerable light on this subject of carbonic acid- p_H system by reference to the work of Johnston,²⁰ Johnston and Williamson,²¹ McClendon,²² Massink,²³ Heymann,²⁴ Greenfield and Baker,²⁵ and Ross and Bagchi.²⁶

Dec. 27, 1920—An experiment was tried with the effluent of the mechanical filtration plant, which had,

of course, previously been coagulated as part of the usual system of purification. This test was naturally more severe than that described above. The sample was acidified and was left over night in a closed bottle. On the following morning it was filtered through paper. No reaction for Al was obtained in the filtrate. The experiment was not conclusive, for the check sample without acid, when filtered, showed a decidedly less pronounced reaction than usual, although by no means alumina-free.

Jan. 6, 1921—For the sake of brevity, we shall refer to the samples described on Dec. 15, 1920, as: *A*. Slow sand water—alum treated—acidified. *B*. Slow sand water—alum treated—not acidified. On Jan. 6 portions of these waters were again withdrawn. Filtration of the two samples showed the presence of alumina in both, but less in *A* than in *B*. On testing, *A* was found to have become alkaline. This would indicate that the p_H had risen again well above the isoelectric point, and therefore the alumina could not be filtered off, since it had gone into solution once more.

The flock in *A* was more compact and granular and had a faint brown tinge. The flock in *B* was slimy looking and with very indefinite boundaries. The supernatant water in *A* had no observable haze, while that in *B* had a trace of faint haziness (such as is often observed in mechanical filter effluents). The flock in *B* had no trace of brown tinge. The filtration of *A*, as before, was much more rapid than that of *B*.

Jan. 7, 1921—A preliminary series of experiments was carried out in order to shed some light upon the possibility of side reactions in use of alum in water.

TABLE III. POSSIBLE SIDE REACTIONS IN ALUM TREATMENT OF WATER

Sample Number	Slow Sand Effluent				Rapid Sand Effluent— Each Contained ½ g.p.g. Alum			
	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>	<i>A</i>	<i>B</i>	<i>C</i>	<i>D</i>
Amount water used, c.c.	250	250	250	250	250	250	250	250
Acid added (1 c.c. conc. HCl)	Yes	Yes	No	No	Yes	Yes	No	No
BaCl ₂ added (1 c.c. 10%)	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Degree of precipitation	3	3	1	1	4	4	2	2
1—Minimum; 4—Maximum								

In each of four clean 500-c.c. bottles was placed 250 c.c. slow sand effluent; in each of four more similar bottles, 250 c.c. rapid sand effluent already treated at rate of 0.5 grain per imperial gallon. These various samples were treated as shown in Table III. The following tentative hypotheses appear:

(a) The sulphate in the slow sand water (known, it may be observed, to contain alumina, in a non-reacting form) is "masked" to a marked extent at the natural p_H .

(b) Of the added sulphate ions derived from the alum, a notable proportion is masked at the natural p_H .

(c) This effect would be explained if we assume that in the presence of OH-ion non-ionized calcium aluminosulphate is formed. This is known to be unstable in presence of H-ion.

Jan. 24, 1921—In each of six clean glass-stoppered bottles of 1 liter capacity, 1 liter of recently filtered slow sand water was added. Of these, *A1*, *A2*, received each 0.6 c.c. normal sulphuric acid. *B1*, *B2*, received 0.4 c.c. acid. *C1*, *C2*, received no acid. One grain per imperial gallon of alum added to each of the above six samples. Allowed to stand two hours after once thoroughly shaken. No difference in appearance of the six.

From *A1*, *B1*, *C1*, respectively, two successive portions of 50 c.c. were withdrawn and filtered through single thickness Whatman No. 1 paper. Tested for alumina in these six portions with one drop hæmatoxylin, fol-

lowed after a short interval by two or more drops N/6 acetic acid.

Results—*A1*, both portions alike; brownish shade before acetic acid, clear yellow after; no trace of alumina. *B1*, both portions alike; tint before acid hard to describe; there was, however, a faint trace of blue; after acid a clear yellow with just the faintest tinge of brown, which would probably escape detection without close comparison; a trace of alumina, certainly under 0.2 p.p.m. *C1*, both portions alike; blue before acid; brown after; heavy trace of alumina (0.3-0.5 p.p.m.).

Jan. 25, 1921—Withdrew a third 50 c.c. from *A1*, *B1*, *C1*, filtered through the same three papers as before, each through its own paper to avoid adsorption effects. Result same as before. In size of flock and rapidity of clearing, descending order was *A1*, *B1*, *C1*. In the undisturbed bottles the same order was observable—*A2*, *B2*, *C2*. These lagged behind their duplicates on account of agitation in the latter. Filtered off about half of what was left of *A1*, *B1*, *C1*, into Erlenmeyers of 600-c.c. size with view to further experiment.

Jan. 26, 1921—*A1* filtered and tested practically alumina-free. The water was filtered during the course of the day in small lots at a time. The faintest possible indication was obtained, due in all probability to the prolonged filtration in small lots having shifted the p_H .

Feb. 5, 1921—Unfiltered and filtered *A1* tested for alumina. Unfiltered gave strong reaction; filtrate none or negligibly small.

CONCLUSIONS

Theoretical considerations, supported by experimental results obtained in water work and elsewhere, appear to demonstrate fairly completely that the reaction of aluminum sulphate with the natural alkalinity of a water is a complex mobile transformation. The reaction seems to be delicately dependent upon the actual alkalinity of a water, its hydrogen ion concentration, rather than upon its potential alkalinity. The hydrogen ion concentration in turn is regulated to a large degree by carbon dioxide equilibria. Evidence so far accumulated seems to indicate that complete precipitation of $Al(OH)_3$ takes place at a hydrogen ion concentration somewhere near the neutral point, p_H 7.0, unless disturbing or buffer influences are operative. Outside of this zone of favorable alkalinity re-solution of insoluble flock occurs to a greater or less degree.

It seems clear, from the above considerations, that the appearance of aluminum compounds in filter effluents should not be accepted as due to faulty operation, according to orthodox interpretations, but to failures due to misunderstanding of the reactions involved. This statement is given in the nature of a hypothesis, to be substantiated by further experimental evidence. If the hypothesis is found to be true, the problem of residual alumina, not only in filter effluents, but in all coagulated waters, may be attacked from a new angle.

The writers have studiously avoided any reference to the sanitary, physiological or economic importance of the passage of soluble aluminum compounds through filters. That it has a great practical importance, however, the little data we now have apparently confirm. Owing to the controversial nature of the subject, it appears best to reserve discussion of this phase until more accurate and complete evidence is available.

In the meantime, the writers have presented here a modification of current theory as to alum action. If we are pressed as to its practical importance, we can only

respond with that learned Frenchman Charles Richet, who said, before the Physiological Congress in 1920, in Paris:

"Seek to understand things; their utility will appear later. First of all it is knowledge which matters."

Legal Notes

BY WELLINGTON GUSTIN

Plea of Set-Off Good Where Company Sold Product Exclusively Contracted For by Another

The Supreme Court of Appeals of West Virginia recently decided some interesting points raised in the litigation brought by the Cook Pottery Co. against J. H. Parker and others, partners. (104 S. E., 52.)

The action was begun upon promissory notes of defendants, who filed two special pleas of set-off and a notice of recoupment against the pottery company. In each of the pleas defendants pleaded and relied on a contract between them and the company whereby plaintiff was permitted to manufacture a certain product, which was then owned and controlled by defendants, the same to be sold exclusively to the defendants, and to be invoiced to them at a named price, and with the further agreement on part of the plaintiff that it was to add to the aforesaid price the sum of 24c. per thousand to be credited to the account of defendants in reduction of their indebtedness. This agreement was for five years and as long thereafter as either party to it did not violate the provisions thereof, then to be canceled at the option of the party who had not violated the provisions thereof.

BREACH OF CONTRACT CLAIMED

In the first special plea the breach of contract claimed and the matter of set-off relied on by defendants was that prior to the action the pottery company had sold directly to other persons large quantities of the goods, and on all these goods defendants claimed royalty of 24c. per thousand, amounting to \$7,200.

In the second plea defendants relied on the same breaches of contract, but instead of the royalty or rent of 24c. per thousand on the goods manufactured and sold to others they claimed the right to offset against plaintiff's claim the difference between the contract price at which the goods were to be billed to defendants and the price at which they were actually sold by plaintiff to other persons, amounting to \$45,000, the profits realized by plaintiff in excess of the price at which they were to be manufactured, sold and delivered to defendants.

The court points out that the first objection made to both pleas is that the agreements are not alleged to be in writing, because if not in writing plaintiff would have a right to rely on the statute of frauds, requiring a writing. But a contract in writing need not be pleaded as such, for if the other party thereto wishes to avail himself of the defense of the statute of frauds he may urge it as an objection to receiving oral evidence of the agreement on the trial.

CLAIM FOR ROYALTY NOT UNLIQUIDATED DAMAGES

Again, it was contended that the matters set out in both pleas were not averred to have originated in or as growing out of the contract sued on, and that both amount to claims for unliquidated damages. It was said that an unliquidated claim for damages can not be set off against a liquidated demand, but if a plea of set-off pleads a claim not resting in uncertainty but is sus-

ceptible of accurate calculation as provided by the contract it may properly be filed, and is improperly rejected.

The first plea amounts to a demand for royalty at the rate of 24c. per thousand for the right to manufacture a product the rights to which are owned and controlled by the defendants. True, the quantity manufactured was not stated, but this was unknown, and it was averred that the quantity was sufficient to have aggregated at least the sum of \$7,200. The court says under these facts the amount was merely a question of computation, and the claim was no more unliquidated than if it had been for so many barrels of apples, bushels of corn or the quantity of any other commodity. Unliquidated damages are such as the contract furnishes no means of accurate estimation, but rest in the judgment or discretion of the jury. It is not necessary that the price should have been agreed upon when goods are sold. This fact does not render the claim unliquidated in the sense that it cannot be offset against the demand of the other party. This plea of set-off was held to be good in law. (8 Ann. Cases, 736.)

NO RIGHT TO PROFIT ON GOODS SOLD

The second plea averred a claim for damages, being the difference between the price at which plaintiff agreed to manufacture and sell the product to the defendants and the price at which the plaintiff itself sold them to others, an amount unascertainable from any facts alleged or known method of calculation. It was claimed that plaintiff manufactured and sold a particular quantity of the goods, but the court said defendant had no right to the profit made by plaintiff on the goods manufactured and sold by it. The measure of defendants' damages is what they could or would have made if the pottery company had kept its contract to make and deliver the goods to them at the stipulated price. But such cannot be made the subject of a plea of set-off against the plaintiff who brings his suit on a separate and distinct demand. The profits which defendants might have made on such goods if plaintiff had fulfilled his contract were too remote and speculative to be the proper subject of set-off. Therefore this plea of set-off was held not good. (51 W. Va., 523.)

CLAIM OF RECOUPMENT A VALID ONE

Further, the court held that defendants had the right to file and rely on their notice of recoupment. It was argued against this that the contract for sale and commissions had no relationship to the notes sued on, and that contract did not arise out of the same transaction. The notice alleged an agreement with J. H. Parker & Son in February, 1914, to continue a sale arrangement previously existing upon consideration that Parker would not go into bankruptcy, and that the defendant firm would assume and pay the liabilities of both to the plaintiff, and that the debts would be extended for such time as defendants should be able out of half their commissions earned to pay and satisfy the demands of plaintiff, preferring the open account against J. H. Parker, as stated. Part performance of this contract by defendants was averred and repudiation of it by the plaintiff.

Now the original notes of J. H. Parker were not a part of the same contract set out by defendants, but in so far as any part of the notes sued on entered into the new notes given by J. H. Parker & Son at the time the new contract was made, and when they assumed

the prior indebtedness as alleged, they became a part of the new contract providing for their payment by commissions to be earned, and the court said damages and loss of commissions sought to be recouped against plaintiff's demands by reason of the alleged breach of that contract must be regarded as a claim arising out of the same contract as the notes sued on, and the rule of law applies that when the claim of the defendant arises out of the same contract out of which the plaintiff's demand arose the demand of the defendant, though unliquidated, may be recouped against the plaintiff's claim.

Varnish Drying Patent Held Valid

In a suit brought by the Wenborne-Karpen Dryer Co. against the Rockford Bookcase Co. for infringement of a patent, the patent in question (1,186,477, granted to William M. Grosvenor, June 16, 1916) was held valid and infringed by the District Court of the Northern District of Illinois.

The patent covers a "process for drying and hardening siccative coatings," which consists of simultaneously adding heat and moisture to the air surrounding the siccative coatings. It was alleged by the defendant that substantially the same process has been used for years for the purpose of drying lumber. It was found that too rapid drying of the lumber resulted in the outside becoming case-hardened and steam vapor was therefore introduced into the drying chamber to retard the drying of the outside. As to this point, the court held that there was no analogy between drying wood and drying varnish, since the former is merely the physical process of evaporation, while the latter involves chemical action or oxidation. The phenomena are so different in nature that the discovery that the lumber drying was applicable to varnish drying constitutes a real invention, since the process is not only applied in a different art but with a new and different result. Before the appearance of the Grosvenor process, it was the consensus of opinion that moisture was one of the greatest obstacles to the rapid drying of varnish. For many years prior to the introduction of this process, it required from eighteen to forty-eight hours to harden thick varnish, whereas under the new process the same result was reached in from six to eight hours.

The court also held that the patent was not anticipated by an article on "Pigments, Paints and Painting" written by George Terry in 1893 or by the following patents in the prior art: Schultze, No. 519,352; Victorson, No. 507,512; Gathmann, Nos. 763,387 and 763,388.

The general manager of the defendant's factory admitted that the kiln room was equipped with steam radiators, a pet cock in the steam pipe "serving to let live steam into the atmosphere of the kiln" and an electric fan for the purpose of circulating the air. The claim that the thermometer and hygrometer were not consulted as in the patented process was held not to relieve the infringement.

Consumption of Mercury for Clinical Thermometers

The use of mercury in clinical thermometers does not seem to be a large matter, but the Bureau of Standards estimates that between 3,000 and 10,000 lb. of mercury is so used each year. The average clinical thermometer generally contains about 1 g. of mercury. It is on this basis and with the knowledge of the total production of "clinicals" that the estimate has been made.

An Explosion of Hard Rubber Dust

Results of Investigation of a Recent Explosion in Reduction of Hard Rubber Scrap Department of a Large Industrial Plant—Recommendations for Prevention and Precautions to Be Taken in Hard Rubber Grinding

By DAVID J. PRICE* AND HYLTON R. BROWN†

THE fact that practically any kind of combustible dust will explode with violence under favorable conditions when mixed with the proper proportion of air and ignited by a flame or spark has been known for some time. Several recent explosions in factories of the country have shown, however, that some dusts not considered readily combustible are explosive under favorable conditions.¹ An investigation has been made by the Bureau of Chemistry of the U. S. Department of Agriculture of a recent explosion of hard rubber dust in which eight men were killed, one other was injured and property was damaged to the extent of about \$25,000. This article has been prepared to call attention to some of the dangerous practices now followed in the grinding of hard rubber and to suggest methods of minimizing the danger of dust explosion.

REDUCTION OF HARD RUBBER SCRAP

In the case investigated the process followed in the reduction of the scrap rubber was quite similar to the system more or less generally used throughout the country. The scrap rubber is first broken up into pieces about the size of a pea. In some cases this material is heated in large tanks. It is then ground between steam-heated rolls known as refiners or in one of the various types of pulverizers. Sifters are used to sep-

arate any coarse particles from the rubber dust, and this coarse material is returned to the grinders. During this process large quantities of very fine dust are produced which tests have shown will explode violently under favorable conditions. Considerable sulphur dioxide gas is frequently produced during rubber grinding and in many cases no provision is made to remove this gas from the building. In such cases the atmosphere of the grinding department becomes a bluish color while grinding is being done.

EQUIPMENT ARRANGEMENT

In the plant where this explosion occurred the grinding department was located in the basement of a two-story brick building. The space allotted to this work was about 60 x 120 ft. The basement was about 10 ft. deep but only about 6 ft. was below the ground level. Windows were provided above the ground line for light and ventilation. Various types of grinding machines were installed with the motors necessary to operate them. These motors were of different makes, but were all of the squirrel-cage induction type. All switches were of the oil-immersed type and the fuses were of the non-arcing type inclosed in covered steel boxes. The electric lights were of the drop-cord type of installation and were not provided with vapor-proof globes or guards. A suction system was provided to remove the dust from the building. The dust was drawn into hoods located over the grinding machines and then into the fan, whence it was blown through

*Engineer in charge development work, Bureau of Chemistry.

†Assistant in grain dust explosion prevention.

¹CHEM. & MET. ENG., vol. 24, No. 1, pp. 29-32, Jan. 5, 1921; vol. 23, No. 19, pp. 915-920, Nov. 10, 1920; vol. 24, No. 11, pp. 473-475, March 16, 1921.

a 24-in. galvanized pipe into a dust house located on the roof of the building. This pipe ran up the outside of the building and had two right-angle turns—one where the pipe came out of a basement window, and the other where it turned to enter the dust house on the roof. The dust house, which was of frame construction with corrugated metal sheathing, consisted simply of an expansion chamber with a number of muslin bags stretched on wooden frames through which

SIDE AND END VIEWS OF GRINDERS AND HOODS

the air escaped, while the dust fell to the floor of the dust house. The dust produced during the grinding was so fine that a large quantity was drawn into the collecting system, and this made it necessary to clean the dust house frequently.

EXTENT OF EXPLOSION

The explosion, which the evidence indicates originated in the basement, occurred about 4:45 a.m. The first explosion was quickly followed by a second one and some families living near the plant report hearing three distinct explosions. As shown in the photographs, the explosion evidently propagated to the first floor of the building, where the windows, doors and one corner of the brick wall were blown out. It also propagated through the suction system to the dust house, which

DUST COLLECTING SYSTEM

was completely demolished. The building was quite badly damaged by the explosions and the fire which followed, and windows were broken in other buildings of the plant. The fire department, which was called immediately, soon had the fire extinguished and assisted in rescuing the injured. Ten men were employed in the basement and only two escaped. One of the eight men was killed by the explosion and seven received burns from which they died later at the hospitals to which

they had been taken after the disaster. Several men were employed on the first floor above the section of the basement where the explosion occurred, but they were uninjured.

Two of the workmen were found in the southwest corner of the basement, where they had evidently been blown by the force of the explosion. This fact was taken into consideration during the investigation to determine where the explosion started and what caused it. While the evidence apparently establishes the fact that the explosion started in the basement, it has been impossible to determine definitely what caused the original ignition. Practically all evidence which would have assisted in establishing this point was destroyed by the explosion and fire. The two men who escaped from the basement were unable to give any information regarding the point of origin or cause of the explosion. From the effect of the explosion on various parts of the building and the equipment in the basement it is believed that the explosion started in or near one of the grinding machines.

THEORIES AS TO CAUSE OF EXPLOSION

A number of theories have been advanced as to the cause of the explosion: (1) The dust may have been

VIEW SHOWING DISRUPTED WALLS

ignited by sparks formed when some foreign material entered the grinding machine with the scrap rubber. It is known that pieces of metal are frequently found in scrap rubber, and explosions in other industries have been caused by sparks formed when metal entered the grinding machine. (2) An electric light may have been broken accidentally and the dust ignited by the hot filament. Experiments have definitely established the fact that explosions can be started in this way.³ In this explosion the wires and light fixtures were so badly burned or damaged by the explosion and fire that it was impossible to determine whether or not a broken light caused the ignition of the dust. (3) Static electricity often accumulates on moving machinery and unless the machine is properly grounded the charge is built up until it becomes strong enough to break down the air gap and jump to some other machine or a ground. Sparks formed in this way will ignite certain dusts, but in this case no static electricity had ever been noticed on any of the machines. It is therefore considered improbable that a static spark was responsible for the ignition of the dust. (4) A lighted match would ignite the dust. Since in this case eight

³Electrical Review, vol. 78, No. 5, Jan. 29, 1921, p. 180.

of the workmen were killed and the two others were unable to give any information as to the cause of the explosion, it is impossible to substantiate the theory that a lighted match started the explosion. (5) Explosions have been started by sparks in dust-collecting fans when the blades struck some metallic substance entering the fan or when the blades became loose on the shaft and struck against the fan casing.³ In the investigation of this explosion special attention was given to the condition of the fan after the explosion. It was found that the side of the fan casing where the suction pipe from the dust hoods entered the eye of the fan was blown completely off. The exhaust pipe from the fan to the dust house was blown apart at both elbows. The dust house on the roof of the building was completely destroyed, as shown in the photograph. It had been cleaned about midnight, or approximately four hours and forty-five minutes before the explosion occurred. It is estimated that at the time of the explosion the house contained about 125 lb. of dust.

ORIGIN OF EXPLOSION

The fact that so much damage was done to the fan and exhaust pipe would indicate that the explosion had built up considerable force by the time it reached this point in the system. It is believed that the explosion originated in or near one of the grinding machines and was caused by foreign material entering the grinder, by a broken electric light, or by a lighted match. The flames propagated throughout the basement, where the employees were severely burned, and extended to the first floor, where the windows and one corner of the wall were blown out. The flames entering the suction hoods flashed through the suction pipe to the fan, where they met their first obstruction and built up the pressure which blew out the weakest side of the casing—the one containing the inlet opening. The flames also propagated through the fan into the exhaust pipe, built up sufficient pressure at each bend to rupture the pipe and continued into the dust house on the roof of the building, where enough dust was present to cause an explosion which completely wrecked the house. It must be remembered that this is only a theory of what happened during the explosion built on the knowledge obtained during investigations of previous explosions in industries where the conditions and some of the installations were similar to those in the hard rubber grinding industry.⁴

RECOMMENDED PRECAUTIONS IN HARD RUBBER GRINDING

This explosion proves very conclusively that grinding hard rubber is a dangerous process and indicates very clearly some of the precautions which should be taken to guard against explosions. In other industries, particularly feed manufacturing, it has been necessary to give special attention to the prevention of explosions in the oat hull grinding department. It is believed that the methods adopted in this industry will be equally effective in preventing damage from dust explosions in grinding hard rubber:

1. The grinding department should be segregated from the remainder of the plant and if possible operated independently of other units.

2. The building containing the grinding department should be of heavy framework with light walls and roof so as readily to permit the release of pressure from the building should an explosion occur. Large window area serves this purpose very well and the modern daylight construction is recommended.

3. Good ventilation should be provided and where gases heavier than air are produced during the process the air should be drawn out of the room near the floor and fresh air admitted near the ceiling or roof.

4. Where fine dust is produced during the process an efficient dust-collecting system should be installed. The old-style dust room, where large clouds of dust are in suspension, should be eliminated if possible or

REMAINS OF THE DUST HOUSE

located at a safe distance from the main building. The dust should be collected as near as possible to the point of origin and conveyed through pipes with as few turns as possible to the collector, which should be located outside of the building or vented to the outside air. If sharp turns are necessary in the pipe line inside the building, it is often advisable to provide a vent at the bend leading to the outside air with a cap which will be blown off should any high pressure occur at this point. Drawing explosive dusts through a fan should be avoided if possible. A suction through the collector or an induced-air current is preferable.

5. Special precautions must be taken to see that no metal enters the grinding machines. This is the only way to guard against ignition of dust by sparks struck in the machines. A vent leading directly from the machine to the outside air often assists in preventing a disastrous explosion by providing a direct means of escape for the primary explosion within the machine.

6. In places where clouds of explosive dusts are produced electric lights should be inclosed in vapor-proof globes and properly guarded to prevent accidental breakage. All switches and fuses or electrical equipment in which sparks might be produced should be located in a separate room or at least inclosed in fire-proof and dustproof boxes.

7. Rules against smoking and carrying matches in sections of a plant where conditions are favorable for a dust explosion must be rigidly enforced and special attention given to the prevention of hot boxes on machinery operating in dusty atmospheres.

8. Cleanliness is the best general precaution to adopt for the prevention of dust explosions. A disastrous dust explosion cannot occur in a clean plant,

³CHEM. & MET. ENG., vol. 23, No. 19, p. 915.

⁴Proceedings of Conference of Men Engaged in Grain Dust Explosion and Fire Prevention Campaign Conducted by U. S. Grain Corporation in Co-operation with Bureau of Chemistry, U. S. Department of Agriculture, July, 1920.

because the flames cannot propagate unless dust is present to be mixed with the air in sufficient quantity. From 0.02 to 0.04 oz. of dust per cu.ft. of air is usually sufficient to form an explosive mixture. The plant should be kept scrupulously clean, especially overhead structures where dust accumulations could be thrown into suspension in the air by a sudden jar or shock.

The increase in the number of industries in which the danger of dust explosion is present makes it imperative to conduct further research and investigational work. The various explosive dusts ignite at different temperatures, and different amounts of the various dusts are required to form explosive mixtures with air. Perhaps some dusts not now considered dangerous will later be found to be explosive under certain conditions. It may be found necessary to design special equipment to reduce the danger of dust explosions in certain industries. The question of dust explosions in flour mills and grain elevators has been studied for several years by the Bureau of Chemistry of the U. S. Department of Agriculture and the results of this work have been published in bulletins which are available for distribution, but no provision has been made to continue these investigations during the present year. Since it is a question of vital importance to the industries of the country, it is hoped that some opportunity will be presented in the near future to resume the study of dust explosions in flour mills and grain elevators and extend the work to other industries where the same hazard exists.

Plastic Gypsum Plaster

BY WARREN E. EMLEY

A GOOD job of wall plaster is composed of three coats, which are known to the trade as "scratch," "brown" and "finish." The scratch coat is next to the lath, the brown coat in the middle, and the finish coat is applied to the exposed surface to give the plaster a pleasing appearance.

The quality requirements put upon material for the finish coat are peculiar: It must be very plastic in order that it can be spread in a thin layer ($\frac{1}{8}$ in.) over the brown coat, which has set and is partially dry; and it must set in twenty or thirty minutes, in order that the plasterer may finish troweling it without moving his scaffold.

The scratch and brown coats may be made with either plaster of paris ($\text{CaSO}_4 \cdot \frac{1}{2}\text{H}_2\text{O}$) and sand or of lime and sand, but the finish coat must consist of both lime and gypsum plaster. The addition of lime has been thought necessary to give the proper degree of plasticity. As the weight of the finish coat is very small in comparison with the weights of the two other coats, the contractor must provide enough for all three coats and a small amount of lime for the finish coat mixture when gypsum plaster is used. It seems impossible to get good results with a ready mixed lime gypsum plaster. The lime must be soaked with water for at least twenty-four hours in order to develop its plasticity, and the gypsum cannot be soaked, because it sets upon the absorption of $1\frac{1}{2}$ mols of water of crystallization. This means that the materials must be prepared separately and mixed just before being used, thereby requiring extra labor and equipment.

The higher plasticity of lime gives superior sand-

carrying capacity. If lime and gypsum plaster are selling at about the same price, the fact that lime can carry three parts of sand for scratch or brown coat work, while the latter can carry only two, makes the lime plaster much cheaper. At the same time, the superior plasticity of the lime may reduce the labor cost of application of the plaster considerably below that of the gypsum plaster.

From the above statements it will appear that if a plastic form of gypsum plaster can be made without the use of hydrated lime, the differential in favor of lime, due to its greater sand-carrying capacity, will be overcome. Also it will not be necessary for the gypsum manufacturer to add lime or any other foreign material (except retarder) in the preparation of neat gypsum plaster. These results are greatly to be desired, not only by the gypsum industry, but also by the general public, because they would tend to decrease the cost of an important building material.

Accordingly, work was started on an attempt to make gypsum plaster as plastic as lime. The first successful experiment was completed on Sept. 13, 1920, and since that date sufficient work has been done to make sure of the practicability of the method. The problem may therefore be considered solved, in so far as it can be solved with laboratory equipment.

DEGREE OF SUBDIVISION OF THE HEMI-HYDRATE

The first thought was that plasticity is in some way dependent upon the degree of fineness, and that fine grinding might solve the problem. Fine grinding in itself is not new in the industry, and it would seem strange that any increase of plasticity due to it could have passed unobserved. Investigation has shown, however, that all attempts at fine grinding on a practical scale had been conducted in a buhr or tube mill. It has long been known that the half mol of water of crystallization can be "ground out" of gypsum plaster. When it is reduced in either of the above types of mills, the volume of air passing through the mill carries off the water vapor as fast as it is formed by the frictional heat. If the grinding is sufficient to liberate all of the water, the resultant product is soluble anhydrite. This is a peculiar form of anhydrous calcium sulphate and differs from the mineral anhydrite in its great affinity for water. So great is this affinity that a very short exposure to moist air is sufficient to change it back to the hemi-hydrate. When ground in the usual type of equipment and the frictional heat is not sufficient to liberate the water of crystallization, the size of the grains is not greatly reduced. If the anhydrite is formed, the final product soon absorbs water from the air and the crystals cake into larger aggregates that do not give a plastic plaster.

When calcined gypsum is subjected to grinding under such circumstances that the water is not permitted to escape from the system, an entirely new product results. No satisfactory explanation has yet been evolved, but the fact remains that the product is plastic. Up to a certain limit the degree of plasticity seems to depend upon the duration and speed of grinding.

The plasticimeter described in Bureau of Standards Technologic Paper 169 is not yet adapted to measure the plasticity of unretarded calcined gypsum; the material begins to set before the experiment can be completed. Use has therefore been made of the Carson blotter test, as described in the *Transactions* of the National Lime Manufacturers' Association for 1916.

This has proved quite satisfactory as a means of differentiating between the plasticities of finishing hydrate and masons' hydrate. When tested by this method, this "plastic gypsum" proves to be more plastic than the best lime putty.

BETTER STRENGTH AS WELL AS PLASTICITY

Besides improving the plasticity, the process also causes certain changes in other properties of the material. The increased fineness of the plastic gypsum naturally necessitates the use of more water to bring the paste to a given consistency. Yet, in spite of this excess water, the set material will average about 20 per cent stronger than that made from ordinary calcined gypsum. The process slows down the setting reaction somewhat. The time of set of one sample was changed from twelve to seventeen minutes by this kind of fine grinding. Commercial calcined gypsum usually deteriorates somewhat on storing. It tends to work "lean" and carry less sand. Samples of this plastic gypsum have been exposed to the air for four months without apparent deterioration of their plasticity.

The process has been applied with equal success to calcined gypsums from Nova Scotia, New York and Virginia. It would seem, therefore, that the original quality of the material is of little importance.

GRINDING WORK ABOUT DOUBLED

The laboratory results have been accomplished after calcination by grinding the material in a ball mill constructed so that the water vapor could not escape. Commercial calcined gypsum is always ground during the course of manufacture, either before or after calcination, so that the grinding required to make plastic gypsum does not entail the installation of an extra process. It would seem, however, that the grinding should be done after calcination rather than before to prevent the powder balling up in the mill.

It is probably not essential that a ball mill be used; a buhr mill or tube mill may be satisfactory if there is no loss of water by evaporation during the grinding. It is essential that the product as it leaves the mill shall contain approximately the same quantity of fixed water as commercial calcined gypsum does: 9 parts by weight of water to 136 parts of calcium sulphate, or about 6.2 per cent water.

The duration of grinding required to make plastic gypsum depends upon the kind of equipment used, the fineness and hardness of the material, and the degree of plasticity desired. This problem must be worked out individually by each manufacturer for his particular equipment and material. It is a simple matter to regulate the grinding until the Carson blotter test shows the material to have the desired degree of plasticity. Laboratory experiments indicate that the output will be considerably reduced, perhaps cut in half, if the same equipment is used to make plastic gypsum.

The new product, "plastic gypsum," was demonstrated at the annual meeting of the Gypsum Industries Association on Dec. 15, 1920, but the process of manufacture was not divulged. A patent, covering both the process and the product, has been applied for, and, if granted, will be given to the public for the free use of anyone in the United States. This description of the process is being released at this time in order to give additional protection to the public interest.

Tower Packing Efficiencies

By E. L. JORGENSEN

WHEN devices prove their usefulness in industry through years of service, they are readily accepted as standard and improvements are retarded until retrenchment becomes a matter of great importance. A careful analysis then often shows the way to improvements surprising in their simplicity and importance.

Opportunities for such improvements seem to exist in several branches of sulphuric acid manufacture. In studying construction costs for a chamber acid plant, it is of interest to learn that Glover and Gay-Lussac towers account for from 25 to 40 per cent of the capital expended, and only 5 to 6 per cent of the cost of the towers is for packing.

Considering that in these towers the packing performs all of the active work, the improvement of such packing seems worthy of careful study. If the effect of such packing can be increased, new towers could be built smaller or present towers could be increased in productiveness by re-packing.

GREAT VARIATION IN TOWER PACKING EFFICIENCY

Investigations conducted for this purpose indicate that the effectiveness of tower packings such as they are today can be improved in some cases as much as 100 times.

The factors that control the effectiveness of tower packing are the area of contact surfaces and the length of time of contact between these surfaces and the gases. The length of time depends on the effective space occupied by the gases. If in a cubic foot of packing space one-half of the volume is dead space occupied by packing and one-half active space occupied by gas, then each cubic foot of gas passing through per second will be exposed to the contact surface for one-half second.

EMPIRICAL CALCULATIONS

The influence of contact surface and of time of contact can be mathematically expressed as follows:

Capacity, $C_1 = 0.3706C$;

$C = s \times v$;

s = sq.ft. of contact surface per cu.ft. of packing space;

v = cu.ft. of active space per cu.ft. of packing space.

This formula has been applied to a number of tower packings in use today and to new forms of packing that have suggested themselves as a result of these investigations. The results are given in the accompanying table and the arrangements are illustrated in the figure.

In the table of values for C_1 , the factor 0.3706 is based on a well-known packing built as checkerwork of 9-in. straight brick placed 9-in. on centers. This serves to facilitate comparison.

When applying higher mathematics to the problem it is found that with packing made of plane-parallel bodies the maximum of effect is reached when the active space and the dead space, or the space occupied by the packing itself, are the same.

To increase the effect of towers of today without increasing their size or to reduce the size of a new installation it is necessary to resort to thinner shapes.

To facilitate the use of thinner shapes means of equal spacing and of maintaining stability must be provided.

ARRANGEMENT FOR TOWER PACKING

Fig. 1. 9-in. straight brick on edge 9-in. centers. Fig. 2. 9-in. straight brick flat 9-in. centers. Fig. 3. 9-in. split brick 2.5-in. centers. Fig. 4. Brick checkerwork. Fig. 5. $\frac{1}{2} \times 5 \times 10$ -in. tile. Fig. 6. Detail of tile provided with semi-circular, square, triangular or other type notches at foot and with top edge to correspond to the notches, also with knob for proper spacing. Fig. 7. Detail of tile with notches of any shape at head and foot for proper spacing. Fig. 8. Detail of tile with holes and dowels for proper spacing. Fig. 9. Detail of tile with knobs of any form for proper spacing.

To accomplish this a number of suitable interlocking devices are suggested, as shown in the illustrations.

Lunge in his book on "Sulphuric Acid and Alkali" states that coke-packed towers have only one-twentieth to one-fortieth the capacity of towers packed with so-called Lunge plates. Lunge plates upon mathematical analysis show a capacity of only 41.2 per cent of a packing made from 9-in. straight brick placed 9-in. on

If the channels or passages for gas are uneven, a rush of gas will go through the larger openings or channels, where the area of contact surfaces is smaller. The descending liquid will be diverted to the locality where the surfaces are largest and the gas passages and the pieces of packing are smallest. Carrying this reasoning to the extreme, the case may arise when all liquid passes through the smallest channels, completely filling them, and all gas through the largest channels, with the result that the effect of the tower is reduced to a minimum. This explains the small amount of work done by towers packed with coke or quartz.

This weakness exists in a number of tower packings in vogue today where gas passages are not of uniform size. A slight disturbance of the balance between flow of gas and contact surfaces is enough to cause great decrease in the effect of the packing.

Attention is invited to the figures given before, showing the high cost of towers and the low cost of packing, and to the figures of the table showing the possible improvements upon today's practice.

Records show the sulphuric acid production of the United States to have been equivalent to about 6,000,000 tons of 50 deg. Bé. acid per year. Taking the cost of the plants to produce this acid to be approximately \$120,000,000, the cost of towers for these would be about \$40,000,000.

These figures would seem to warrant most careful study and sincerest consideration for more effective packing for new towers as well as for the re-packing of existing installations, in all chemical industries where the contact between gases and liquids is of predominant importance.

centers, and coke and quartz packing therefore have only 2 to 4 per cent of the capacity of the brick packing.

This brings out a third and even more important factor influencing the effectiveness of tower packings. The flow of gas must be even and equally distributed in all parts of the packing so as to give a perfect balance between contact surfaces and flow of gas.

The Problem of Reorganization of the Federal Government*

BY HERBERT C. HOOVER

THERE is one problem of the new administration that has received the attention and thought of the organized engineers of America for many years past. This is the problem of the reorganization of the federal government. The inadequacy, the wastefulness and the inefficiency of our federal organization was evident enough under pre-war conditions. These inadequacies, these inefficiencies, these wastes were exhibited to the country during the war at the cost of millions.

Congress has placed the problem in the hands of a very able Congressional joint committee. But if this joint committee succeeds in securing the imminently necessary results it will only be by full insistent support to it by public opinion. Many attempts have been made at reorganization before, but all of them have gone to the same crematory—the interminable differences in opinion among the executive and legislative officials over details.

To any student of federal organization one sweeping and fundamental necessity stands out above all others, and that is that the administrative units of the government must be regrouped so as to give each of the great departments more nearly a single purpose. The hodge-podge of aims in certain administrative branches is scarcely believable when we consider our national pride and skill in organization. Such functions as public domain, public works, assistance to veterans, public health functions, aids to navigation, to industry, to trade, purchasing of major supplies, are each and every one scattered over from four to eight departments, most of which are devoted to some other major purpose.

HOW TO PERFECT ECONOMIES

Economies can be accomplished from a public point of view by an elimination of the overlap in these different units of administration through unification into groups of similar purpose. The real economy to the nation, however, does not lie here, however great this may be, but it lies in their more effective functioning in their daily relation to the public. The extra cost imposed upon business in general in the determination of the relation of any particular business to the different functions of the government, with the unnecessarily duplicating interferences and demands, is a real charge on national wealth, probably as great in some directions as the actual costs of the administrations themselves.

Of equal importance with economy is to secure effective concentration of government effort into service to the community. No constructive vision or policies can be built around a national service directed by from two to ten Cabinet members, more especially when this particular purpose is a side issue to all of them. No better example of this exists than the deplorable handling of our relations to our veterans.

There are other reasons that render reorganization imperative. The changed economic situation of the world demands that the functions of the government in aid to commerce and industry be given more concentration and wider scope.

The enlarged activities of the government as a result of the war greatly affect certain departments. The

Treasury today as the fiscal office of the government must handle an annual budget of \$5,000,000,000 as compared with \$1,000,000,000 before the war. Activities of the Army have increased from a budget of \$200,000,000 to \$400,000,000; activities of the Navy have increased from a budget of \$125,000,000 to \$425,000,000. Thus the burden and responsibilities for the major purposes of these departments have been enormously increased. I believe it is the consensus of the gentlemen conducting these departments that in the interests of efficiency they should not be called to responsibility for the administration of at least some of the matters not pertinent to their major functions which clutter their departments.

We have also some confusion between executive, advisory and semi-judicial functions. One of the tendencies of government both local and national during the last twenty years has been to add executive functions to commissions and boards created primarily for advisory or regulatory purposes. It requires no argument with our business public that the executive functions cannot rise to high efficiency in the hands of government boards where from the very nature of things each member has a separate responsibility to the public and is primarily engaged in a semi-judicial function.

Furthermore, during the last few years there has been a great growth of independent agencies in the government reporting directly to the President until his office is overburdened almost beyond the point of endurance. The original and sound conception was that the executive functions should be reported up to the President directly through his Cabinet officials. Not only do these outside functions today overburden the President but they render co-ordination with executive departments extremely difficult. It is neither possible nor advisable to place all these outside organizations into the departments, but much could be done to mitigate the situation.

One of the great steps in federal reorganization is the erection of a budget system, with its necessary reorganization of the Congressional committees. There can be no doubt as to the early accomplishment of this great reform, but it will not serve its real purpose until the departments have been reorganized so that they represent a common purpose. Without this Congress will never have before it budgets showing the expenditure of the government in its relation to any particular function.

TRIALS OF THE MARINER

I have daily evidence in the Department of Commerce of all these forces. The question of governmental aids to navigation is not by any means one of the principal functions of our government, but it must be a sore trial to the hardy mariner. He must obtain his domestic charts from the Department of Commerce, his foreign charts from the Navy Department and his nautical almanac from the Naval Observatory—and he will in some circumstances get sailing directions from the Army. In a fog he may get radio signals from both the Navy and Commerce, and listen to foghorns and look for lights and buoys provided him by Commerce; if he sinks his life is saved by the Treasury. He will anchor at the direction of the Army, who rely upon the Treasury to enforce their will. His boilers and lifeboats are inspected by the Department of Commerce; his crew is certificated by one bureau in Commerce, signed off in the presence of another and inspected at

*Address delivered at the dinner given in Mr. Hoover's honor by the Philadelphia Engineers Club, April 16, 1921.

sailing by the Treasury and on arrival by the Department of Labor.

It is possible to relate the same sort of story in our governmental relations to industry to our domestic and foreign commerce.

The moral of all this is that economy could be made by placing most of these functions under one head, not only economy to the government but to the mariner. Congress would know what it spends in aid to navigation and the government could develop definite policies in giving proper assistance, and lastly could remove from the hardy mariner's mind his well founded contempt for the government as a business organization.

The economic changes in the world, growing out of the war, and their reflex upon our trade and industry make it vital if we are to maintain our standards of living against increasing ferocity of competition that we shall concentrate and enlarge our national effort in the aid, protection, stimulation and perfection of our industrial and commercial life. There can be no real Department of Commerce or commercial policies to these broad purposes so long as the instrumentalities of the government bearing on these questions lie in half a dozen departments.

The Magnesite Industry in 1920

THE production of magnesite in the United States in 1920 increased 94 per cent in quantity over that of 1919. The entire output was made by two states, California and Washington. California mined 63 per cent more magnesite in 1920 than in 1919 and more than eight times as much as it mined seven years ago. Washington increased its production 109 per cent over that of the preceding year, making by far the largest output it has yet made.

According to the United States Geological Survey the total production of magnesite in the United States in 1920 was 303,767 short tons, which was valued at approximately \$2,748,150. The following table shows the production by states:

CRUDE MAGNESITE PRODUCED AND SOLD OR TREATED IN THE UNITED STATES, 1913-1920

Year	California		Washington	
	Quantity (Short Tons)	Value	Quantity (Short Tons)	Value
1913	9,362	\$77,056		
1914	11,293	124,223		
1915	30,499	274,491		
1916	154,259	1,388,331	715	\$5,362
1917	211,663	2,116,630	105,175	783,188
1918	84,077	761,811	147,528	1,050,790
1919	50,020	504,973	106,206	743,442
1920	81,782	1,083,262	221,985	1,664,888

Most of the output of California was calcined and used as plastic material, only a small part being natural ferromagnesite, used as a refractory lining of steel furnaces on the Pacific Coast. On the other hand, practically all the magnesite mined in Washington was dead-burned into synthetic ferromagnesite and used as a refractory lining of furnaces and smelters.

The largest producers in California were the Tulare Mining Co. and the Sierra Magnesite Co., at Porterville; the White Rock mine, operated by Frank R. Sweasy, in Napa County, and the property of the Western Materials Development Co. on Red Mountain, operated by C. S. Maltby.

The Northwest Magnesite Co., of Chewelah, Wash., was the largest producer in the United States. It shipped in 1920 more than 90,000 tons of dead-burned ferromagnesite, most of which was sent to steel com-

We want no paternalism in government. We do need in government aids to business in a collective sense. In a department we do not want either to engage in business or to regulate business. We need a department that can give prompt and accurate diagnosis from both a foreign and domestic point of view of economic events, of economic tendencies; of economic ills; that can promptly and accurately survey economic opportunity, economic discrimination and opposition; that can give scientific advice and assistance and stability to industry in furnishing it with prompt and accurate data upon production, supplies and consumption; that can co-operate with it in finding standards and simplifications; that can by broad study promote national conservation in industry and the elimination of waste; that can study and ventilate the commercial side of our power possibilities; that can study and advise national policies in development of rail, water and overseas transportation; that, in fact, covers, so far as government functions can cover, the broad commercial problems of trade, industry and transportation.

This can be accomplished more by co-ordination of existing governmental facilities than by increased expenditures.

panies and manufacturers of refractory products east of the Mississippi. The American Mineral Production Co., of Valley, Wash., sold its output crude to the Northwest Magnesite Co., whose quarries are near by. The Western Materials Co. operated the Double Eagle magnesite mine, near Valley, and shipped the calcined product to the American Refractories Co.

At the end of December, 1920, all the operations in Washington were stopped, principally, it is believed, on account of a lack of orders from the steel companies, many of which were idle or were not working full time. Some of the California producers were considerably discouraged at the end of the year on account of the high cost of labor and supplies, the high freight rates, and the competition of foreign material.

The imports of magnesite in 1920, reported by the Bureau of Foreign and Domestic Commerce as calcined, not purified, amounted to 43,154 long tons, valued at \$780,078. These imports came from the following countries:

MAGNESITE IMPORTED INTO THE U. S., 1920

Quantity (Long Tons)		Value	Quantity (Long Tons)		Value
Austria		\$4	Scotland	190	13,720
Germany	713	28,566	Canada	6,028	184,060
Italy	21,185	241,220	Mexico	500	6,300
Czecho-Slovakia	3,829	126,827	Venezuela	2,300	11,500
Greece	4,000	38,418	Australia	34	417
Turkey in Europe	3,528	70,540	Straits Settlements		4
Netherlands	819	54,991			
England	28	3,511			
				43,154	\$780,078

The magnesite imported from Italy was mined in Austria, and that from Czecho-Slovakia was obtained from the former Hungarian deposits. That imported from Mexico came from Santa Margarita Island and was calcined near San Diego, Cal. A shipment from Greece received in November was the first sent from that country since 1916. The arrival of 2,300 tons from Venezuela in September, 1920, was a notable event, as the recorded imports of magnesite from that country are meager.

Although the quantity of magnesite imported in 1920 was nearly three times as great as in 1919 it was only about one-seventh of the quantity commonly imported before the war.

Structure of Tungsten Steels

Review of Honda and Murakami's Work, Presenting Their Principal Conclusions as to the Structure and Constitution of Tungsten:Iron:Carbon Alloys—Reactions Between Iron Tungstide and Iron and Tungsten Carbides Are Responsible for Great Complexity

THE effects of tungsten in steel have been studied by many investigators, among them being Osmond,¹ Carnot and Goutal², Sir Robert Hadfield³, Böhler,⁴ Guillet,⁵ Swinden,⁶ Arnold and Read,⁷ and Honda and Murakami.^{8,9} The last-named investigators have carried out by far the most complete study of such alloys, and it is their work that will be largely here reviewed. As a result of their work with magnet steels containing from 0.35 to 0.60 per cent carbon and 4.8 to 6.2 per cent tungsten they reached in the main the following conclusions:

1. The presence of two carbides, Fe_3C and WC , in magnet steel as found by Arnold and Read is very probable. They can exist separately or as a double carbide, depending upon the heat treatment. After once heating to 800-900 deg. C. and slowly cooling, the two carbides exist as a double carbide.

2. Above A_{c1} this double carbide decomposes into its components, both dissolving in austenite and so remaining up to about 900 deg. C. On further heating the tungsten carbide dissociates into carbon and tungsten, both remaining in solid solution, while the tungsten dissolved in the austenite forms an iron tungstide Fe_2W . Degree of dissociation increases with rise in temperature, being practically complete at 1,100 deg. C.

3. By normal cooling from above 1,100 deg. C. the A_1 , A_2 and A_3 transformations are lowered to a temperature below that of the normal A_1 point by the retard-

In their later and more complete study of tungsten steels,⁹ as well as in the investigation of magnet steels, Honda and Murakami largely used magnetic analysis, though this was supplemented by microscopic examination and such other tests as thermal expansion, thermal analysis, etc., where desired. In this investigation the magnetic transformations of cementite and of the double carbide of iron and tungsten occurring respectively at 215 and 400 deg. C. are of considerable interest and importance, for if the magnetization-temperature curve for a tungsten steel shows abrupt changes in the neighborhood of 215 and 400 deg. C. it is evidence that the steel contains respectively cementite and the double carbide, both in a free state.

MAGNETIC ANALYSIS

Applying magnetic analysis then to a series of iron:carbon:tungsten alloys containing from about 0.20 to 30 per cent tungsten and from 0.10 to 1.6 per cent carbon Honda and Murakami found:

I. That in steels containing a given quantity of tungsten—

- A_{r1} and the double carbide transformations increase in magnitude with increase in carbon content.
- The temperature required to lower the A_1 transformation is raised with increase in carbon content.
- The completely lowered A_{r1} transformation has a definite value independent of the carbon content.

II. That in steels containing a given quantity of carbon—

- A_{r1} decreases in magnitude as tungsten increases, vanishing with high tungsten content.
- With increase in tungsten, the retarded A_{r1} is gradually lowered, up to about 9 per cent W. It remains constant with further increase in the tungsten content.

III. That the rate of cooling has a marked effect on the critical ranges. Rapid cooling from below the lowering temperature lowers A_{r1} , while extremely slow cooling from above this temperature does not affect the position of this transformation.

CONSTITUTION

Based on this work, a structural diagram has been constructed which is shown in Fig. 1. Steels showing three transformations at 700 to 770 deg. C., 400 deg. C. and 215 deg. C. are represented by a dot inside a circle, those with two at 700 to 770 deg. C. and 400 deg. C. by a cross, and those having a single transformation at 750 to 780 deg. C. by a dot. Free constituents (as bracketed) in each of the six regions are given in the tabulation directly above the diagram. Magnetic transformations at 700, 400 and 215 deg. C. reveal respec-

FIG. 1. STRUCTURAL DIAGRAM FOR TUNGSTEN STEELS

ing effect of the tungstide (Fe_2W) dissolved in the austenite. At about 550 deg. C. the retarded A_3 transformation begins to take place and with it the ferrite (with dissolved Fe_2W) separates from the solid solution. This continues for about fifty degrees till the concentration of the remaining mother solution reaches such a value that the A_1 transformation takes place at this temperature.

tively the presence of ferrite, double carbide and free cementite, characteristic of steels coming in region I. With increase in tungsten, the free cementite decreases and finally is just sufficient to form the double carbide, when it disappears as a free constituent. As tungsten is further increased the proportion of tungsten carbide (non-magnetic) becomes excessive and it appears in the free state in steels of region II. But two magnetic transformations are obtained at 700 and 400 deg. C.

Steels high in proportions of tungsten and carbon contain free cementite, double carbide and tungsten carbide, for all of the latter does not combine with the cementite to form double carbide. This group of steels, III, may be distinguished from group II by magnetic

FIG. 2. STEEL CONTAINING 2.88 W, 0.19 C, SLOWLY COOLED FROM 860 DEG. C. $\times 120$

analysis. They show three transformations, occurring at 700, 400 and 215 deg. C.

Steels low in carbon with more tungsten than is required to form tungsten carbide (WC) contain iron tungstide, according to Arnold and Read⁷ which is dissolved in ferrite in concentration equivalent to about 9 per cent tungsten. They belong to group IV. Steels in group V have higher tungsten content and more than can be held by the ferrite, so that they contain free tungstide.

Steels of group V with higher carbon form group VI and contain tungstide dissolved in ferrite, free tungstide, double carbide and tungsten carbide. The formula for the double carbide as determined by Honda and Murakami is $4\text{Fe}_3\text{C} \cdot \text{WC}$. Likewise the authors ascribe, after careful study, the lowering of the A_1 transformation in general to the displacements of the eutectic A_1 transformation caused by the tungstide dissolved in ferrite. Since the latter dissolves the tungstide to a concentration equivalent to 9 per cent tungsten the lowering of A_1 will increase with increase in tungsten up to this concentration above which the excess tungsten remains undissolved and, therefore, does not affect the lowering.

FIGS. 3 AND 4. STEEL CONTAINING 4.72 W, 1.57 C
Fig. 3. Slowly cooled from 900 deg. C. Fig. 4. Slowly cooled from 900 to 750 deg. C. and then quenched.

FIG. 6. STEEL CONTAINING 30.04 W, 0.51 C, SLOWLY COOLED FROM 900 DEG. C.

The rate of cooling markedly affects the position of A_1 . Rapid cooling from the lowering temperature or below causes a depression in A_1 while slow cooling from the lowering temperature or above through 700 deg. C. results in the normal A_1 taking place. On normal slow cooling from about 900 deg. C. or other suitable temperature the following reaction occurs:

The higher the initial temperature and the lower the carbon the more this reaction proceeds from left to right. On heating a steel, with lowered A_1 , to above

FIGS. 7, 8 AND 9. STEEL CONTAINING 2.06 W, 0.50 C, SLOWLY COOLED FROM 901, 952 AND 1,005 DEG. C., RESPECTIVELY

FIG. 10. STEEL CONTAINING 22.5 W, 0.27 C, COOLED FROM 1,300 TO 1,100 DEG. C. AND QUENCHED. ETCHED WITH SODIUM PICRATE

A_1 , the reverse reaction takes place, so that on slow cooling the double carbide is again formed.

MICROSTRUCTURE

Normal structure of a tungsten steel may be regarded as meaning that obtained by heating to 850-900 deg. C. for twenty minutes and then cooling at the rate of approximately $\frac{1}{2}$ deg. C. per minute. The normal

structure of hypo-eutectoid steels of low tungsten content belonging to regions I and II are similar to those found in plain carbon steels, consisting of granular ferrite and eutectic matrix,¹⁰ the latter not having the characteristic lamellar appearance of the pearlite of carbon steels (Fig. 2). Increase in tungsten content decreases the proportion of the latter and the ferrite becomes finer than in steels of similar carbon content without tungsten.

Steels coming within region III and hyper-eutectoid steels in region I have primary austenite which does not appear as a network, but as globules, which resemble the ferrite (Fig. 5). They may easily be distinguished from the latter, however, by their coloration in sodium picrate solution. The white globules in Fig. 6 are cementite (colored by treatment with sodium picrate). They are not the double carbide considered by Guillet⁵ to be present in low-tungsten steels of high-carbon content, as the magnetization-temperature curve shows only the A_0 transformation and not that of the double carbide.

Though the steels of region IV contain some carbon, they do not show a eutectic matrix. Probably the carbon exists as WC, with which ferrite does not so combine.

Steels of regions V and VI contain iron tungstide in globular form, but have no ferrite even when the carbon

content is low (Fig. 6). Those of region VI in addition show a eutectic matrix as illustrated in Fig. 5.

Figs. 7, 8 and 9 show the effects of raising initial temperature on the normal structures of a steel containing two per cent tungsten and one-half per cent carbon. Both acicular and granular ferrites appear in Figs. 7 and 8, the former only being present in Fig. 9. Comparison with magnetization-temperature curves for this steel shows that where the normal transformations occur granular ferrite is obtained, and that the steels with lowered transformations show acicular ferrite. Specimens showing both normal and lowered ranges show both types of structure. Granular ferrite is pure iron set free above 700 deg. C., while the acicular type—iron containing tungstide in solid solution—is set free at the lowered A_0 transformation. The formation of such acicular ferrite is due to the simultaneous presence of dissolved tungstide and carbon in iron. The background of these micrographs is considered to be a eutectic of two constituents, first, ferrite containing tungstide and second, cementite. Eutectic structure is shown in Figs. 17 and 18.

By heating steels of region III and hyper-eutectoid steels of region I to about 1,200 deg. C., structural changes similar to those found in hyper-eutectoid carbon steels occur, the cementite appearing as network instead of globules. The globular form of cementite obtained in the normal structure of tungsten steels is ascribed to

¹⁰All etchings are alcoholic nitric or picric acid.

the presence of tungsten carbide. At or above 1,200 deg. C. this WC reacts with iron to form tungstide and cementite. The latter then separates, on cooling, in a network similar to that in ordinary carbon steels.

In a steel containing 4.72 per cent tungsten and 1.57 per cent carbon, cooling from 1,200 deg. C. followed by quenching at 750 or at 650 deg. C. (to find the separation of cementite on cooling) results respectively in production of austenitic-martensite and a network of free cementite, thus showing that Fe_3C separates below 750 deg. C. On the other hand, when cooling from 900 deg. C. cementite has already separated at this temperature (Fig. 4). Dissolved tungstide has therefore a retarding effect on the separation of primary cementite.

The effect of rate of cooling on a steel containing 2.06 per cent tungsten and 0.50 per cent carbon belonging to region VI of Fig. 20 is shown in micrographs of Figs. 11 to 18 inclusive. Very slow cooling from 900 deg. C. results in globular ferrite (Fig. 11), while with more rapid cooling from the same temperature acicular ferrite appears (Fig. 12).

The structures resulting from cooling through 720 to 670 deg. C., from 1,100 deg. C. in twenty, forty and fifty-one minutes are shown in Figs. 13, 14 and 15. They consist of large granular ferrite in network and acicular ferrite in mesh in Fig. 13, less of the latter in Fig. 14 and its final disappearance in Fig. 15, which consists of large granular ferrite crystals and a eutectic matrix. Thus on very slow cooling through 700 deg. C. the tungstide in solid solution reacts with Fe_3C to form free iron and tungsten carbide, a hypothesis confirmed by the magnetization-temperature curve showing both normal Ar_1 and double carbide transformations.

Figs. 16 and 17 are the structures resulting after normal slow cooling from 1,100 to 600 deg. C. followed by very slowly cooling to 540 deg. C. The structures consist of acicular ferrite and a eutectic matrix, showing that a temperature of 600 deg. C. is too low for the change to granular ferrite. Fig. 18, representing the structure of the same steel quickly cooled from 1,200 deg. C. to room temperature, shows fine acicular ferrite.

The effect of rate of cooling is not so marked on steels of region III and hyper-eutectoid steels of region I of Fig. 1, and has little or no effect on those belonging to regions IV, V and VI.

Calcareous Marl Produced in 1920

Reports made to the United States Geological Survey show that 97,487 short tons of calcareous marl, valued at \$322,329, was produced in the United States in 1920. These figures represent an increase of 6.6 per cent (6,050 short tons) over the quantity produced in 1919, but a decrease of 1.5 per cent (\$4,955) in the total value of the product. The average price per short ton was \$3.31 in 1920 and \$3.58 in 1919.

Most of the marl sold in 1920 was used in agriculture, in the same manner as pulverized limestone and agricultural lime, but some was used as a filler in patent fertilizer. In Arkansas, where the product included chalk, a small quantity was sold as whiting, which brought a higher price than the agricultural material.

Nearly one-half of the total output—42,510 short tons—was produced in Virginia and was valued at \$143,373. The other producing states were Arkansas, California, New York, North Carolina, Ohio, South Carolina and West Virginia.

The Treatment of Acid and Alkali Burns*

By A. K. SMITH, M. D.†

THE wounds caused in tissues by acids and alkalis are not strictly burns according to the accepted definition of a burn. Rather such chemicals belong to a class of materials known as escharotics or caustics, substances which when applied to living tissue cause its death and produce an eschar or slough. The strong caustics are sulphuric acid, nitric acid, potash, chloride of antimony, chloride of zinc, acid nitrate of mercury, bromine, chromic acid, lime and hot iron.

Applied to the skin, they immediately unite with it, killing the tissues to a depth proportionate to the strength and quantity of the caustic. Their burn is self-limited and immediately the caustic has exerted its strength by union with the tissues it is no longer destructive.

The burns may be conveniently classified just as burns from heat are classified: A first-degree burn in which only the epidermis is destroyed or inflamed; a second-degree burn extending into the true skin and causing its destruction or inflammation; and a third-degree burn which not alone destroys the skin but also extends into the underlying tissues. The treatment naturally varies with the degree of the burn.

The most important branch of treatment of these caustic burns is prophylaxis or preventive measures, and under this head come all the safety methods observed and the appliances used to render immediate aid in case of accidental spills.

You will notice hot iron classed as a caustic, and many of these innocent-looking liquid acids or solutions of caustic alkalis are quite as harmful as the hot iron.

FIRST AID FOR BURNS

First aid, to be of any great value, must be immediate aid. Probably the most valuable is the shower bath, and of course it must be used before any attempt is made to remove clothing, and every effort must be made to get a large volume of water between the caustic soaked clothing and the skin. Directly after drowning the caustic, saturated watery solution of bicarbonate of sodium may be mopped on the burned area in the case of acid burns, and a 2 per cent solution of acetic acid similarly used in the case of alkali burns. After this has been liberally carried out the patient should be placed in a physician's care.

In simple first-degree burns mopping the burned area with dry gauze and the application of a bland, clean ointment, such as boric acid ointment or burn ointment—which is made of bicarbonate of soda and petrolatum—or oxide of zinc ointment may be used by spreading a liberal layer on gauze and holding it in place with a gauze bandage. Such a dressing relieves the pain and is sufficient with renewal of dressing occasionally.

In second-degree burns the wound should be cleansed of all loose rolled up epidermis, mopped with a mild antiseptic, such as boric acid solution, and an ointment applied on gauze, held in place by a rather loose gauze bandage.

In this degree of burn blisters are encountered.

*Paper presented before National Safety Congress, Milwaukee, Wis., Sept. 29, 1920.

†Manager Medical Section, E. I. du Pont de Nemours & Co., Wilmington, Del.

Small blisters, unruptured, are let alone and larger blisters, where tension is likely to cause pain, are opened by first sterilizing the area with a 3½ per cent alcoholic solution of iodine and a liberal incision is made with a sterile knife near the edge of the blister, allowing its top to collapse and remain. The ointment used in dressing these cases should be absolutely clean, sterile and mildly antiseptic, and should have a melting point that will insure its non-separation on standing in the surgery and still be of such consistency that it will spread with ease.

CARE IN DRESSING AND CLEANING BURN WOUNDS

The dressings are renewed as the judgment of the physician dictates, more often at first, when discharges are profuse; and later at as long intervals as possible, in order to allow healing to progress without disturbance.

The epidermis must grow over wherever it has been destroyed, and this growth takes place from the sound edges of the wound only. The newly formed epidermal cells are exceedingly delicate and are easily torn loose by the removal of a dressing, and it is for this reason that dressings should be changed only when absolutely necessary.

Third-degree burns are cleansed of all loose detritus and dressed with a sterile ointment as in second-degree burns. After three or four days the ointment dressing is replaced by a wet gauze dressing, using a sterile, normal, salt solution. The dressing must be kept wet by repeated applications of the salt solution.

A slough forms in these cases, necessitating a long wait until the sound tissue loosens and throws out the dead material, and all this must take place before healing takes place to any extent.

The use of wet dressings leaves the wound in a very favorable condition for skin grafting, should it become necessary.

The long time required for healing in these cases is due to the slow separation of the slough, and after that has taken place granulation tissue must fill up the sloughed-out spaces and a new epidermis grow to cover the entire area.

Healing may be hastened by a careful removal of portions of the slough when redressings are being made; also by keeping down excessive or exuberant granulation tissue growth; and, most important of all, by skin grafting.

The making of numerous small pin-point grafts, some of which will grow, will reduce the time of ultimate closure of the wound. In some cases larger grafts, by the Thiersch method, may be preferable.

Shock may be an accompaniment of second- and third-degree burns. It should be combated by a hypodermic of morphine, and the earlier it is given the better.

The patient is wrapped in hot blankets and surrounded with hot bottles or hot bricks. Care should be taken to cover the warming bricks or bottles with flannel or other material to prevent burning the patient. Salt solution may be introduced into the system by one of the various methods to increase the volume of blood. Ordinary stimulants given by the stomach are of little value in this condition.

TREATMENT FOR BURNS OF THE EYES

Burns of the eyes by caustics are given first aid by douching the eye with a watery solution of bicarbonate of soda in the case of acid burns and a 1 per cent or

2 per cent solution of acetic acid in alkali burns, after which a piece of boric acid ointment about the size of a pea is put under the eyelid and carefully worked into all corners by gentle manipulation on the outside of the eyelid. Further treatment of the eyes can best be done by an eye specialist.

In giving this, our treatment for caustic burns, I am aware of the various other treatments used in burn cases, many of which are not without good points; but I believe that the treatment as outlined will give the patient quicker relief from pain and quite as rapid a recovery and with as little scarring as any other method.

A Gas-Generating Apparatus

BY ARTHUR W. BULL

IN SPITE of the many descriptions of gas generators found in the literature there are few satisfactory designs for the continuous supply of rather large quantities of gas, especially for hydrogen sulphide, where the offensive odor necessitates a gas-tight apparatus. The ideal hydrogen sulphide generator would be completely automatic; capable of delivering any desired quantity of gas at constant pressure; efficient in the consumption of acid and iron sulphide; odorless; and simple in design. The apparatus shown in the accompanying figure fulfills these conditions with one exception—namely, the gas is delivered with a slight fluctuation in pressure if the demand is discontinuous. For most purposes this is a negligible feature.

No startling innovations are claimed for the apparatus. It is rather a combination of previous ideas resulting in an improved generator using the principles of both the acid spray and the Kipp type.

DESCRIPTION OF THE APPARATUS

A represents the acid container. For this purpose a constant level device of some kind must be used. A portion of an earthenware Parsons apparatus¹ was employed in the original apparatus, but a Mariotte bottle like A' or the arrangement of Browne and Mehling² can be used. The acid enters a small bottle B containing a layer of mercury. This layer acts as a check valve and prevents gas from escaping through the fresh acid. The distance XY must be as short as possible to prevent a siphoning effect. F, the gas outlet, leads to a gas-washing bottle not shown. C and E are tubulated bottles of convenient size and located at the same level. Ten-liter bottles were used, but these were considerably larger than necessary for supplying thirty students with hydrogen sulphide for qualitative analysis. D need only be a 2- to 4-liter bottle. C contains iron sulphide with a layer of broken glass or porcelain at the bottom. Old glass stoppers are excellent. The connecting tubes G should be of 12- or 14-mm. tubing. E is closed by a two-hole stopper with an outlet to the drain. The small bottle H, containing a thin layer of mercury, prevents the escape of hydrogen sulphide from the sludge and at the same time allows an admission of air to break the siphon IJ.

The apparatus is assembled with A empty at any convenient height greater than the desired gas pressure, above E and C. The minimum pressure of gas, in inches of water, desired at F is then decided upon. Six inches is satisfactory for most work. Water is added at E and

¹J. Am. Chem. Soc., vol. 25, p. 231 (1903).

²J. Am. Chem. Soc., vol. 28, p. 838 (1906).

air is allowed to escape through *F* until water just reaches the iron sulphide in *C*. *F* is then closed and *E* is filled with water. *F* is carefully opened and water is allowed to flow from *E* to *C* until the difference between the levels in the two bottles equals the desired minimum head in inches of water. *F* is then closed; *A* is filled with dilute acid and the mercury layer in *B* is adjusted until the pressure of the acid column is just sufficient to overcome the back pressure of the mercury column in *B* and the air pressure in *C*. This is best accomplished by adding slightly more mercury than necessary and then carefully raising *L* until the dilute acid begins to drop on the sulphide. A short rubber tubing insert at *N* facilitates this operation. After the mercury layer is correctly adjusted *F* is opened and the apparatus is ready to function. No further adjustments are necessary and operation is entirely automatic. To obtain hydrogen sulphide open cock *F*. To stop operation close *F*. When assembly is completed the rubber stoppers

the acid is effected. A titration of the sludge in *E* showed that 96 per cent of the acid had been utilized.

A freshly broken piece of iron sulphide was treated with dilute hydrochloric acid until a vigorous evolution of hydrogen sulphide was secured. It was then rinsed with distilled water and immediately immersed in a sample of the sludge. Only a very faint evolution of gas was observed. The sludge is automatically removed through the gas-tight connection with the drain. The difference in specific gravity between fresh acid and the sludge prevents dilution of the partly used acid in *D*.

The chief advantages of the new apparatus are:

1. Its operation is entirely automatic.
2. It uses acid with 96 per cent efficiency.
3. There is no chance whatever for the escape of gas into the room.
4. The apparatus is simple and easily made.
5. Extreme variations in demand are quickly met.
6. Gas can be generated at extremely high rates considering the size of the apparatus.

In case a high gas pressure is necessary, it can be secured by raising bottle *E* and reducing the mercury layer in *B*. The apparatus can of course be used for other gases than hydrogen sulphide.

Morse Hall,
Ithaca, N. Y.

'Time-Punch Feature of Temperature Recorder

It is one thing to settle upon a specific working temperature as being most efficient in a given heat-treating process, but it is quite a different thing to maintain that temperature. No matter how accurate a heat-recording instrument may be, it can do no more than indicate fluctuations of temperature. The human element, untrustworthy at best, must be relied on to see that these fluctuations do not go beyond definite limits. If they do, the whole end and object of a recording thermometer is defeated. To meet these conditions the Schaeffer & Budenberg Manufacturing Co., Brooklyn, N. Y., has devised a time punch as an attachment to its recording thermometers which reduces the uncertainty of the human element to the lowest possible minimum. Making his rounds to inspect the temperature record, the operator in charge of temperature-control now registers the hour and minute of his visit by means of the time punch. Every time a temperature reading is taken he presses a little button and simultaneously a hole is punched in the margin of the revolving chart.

FACTOR OF CHANCE PRACTICALLY ELIMINATED

It can readily be seen that the factor of chance is in this way practically eliminated, because the operative knows that he is being checked. If he shirks his duties, the little punch holes will be conspicuous by their absence. The punch holes are either there or they are not there. If they are not in evidence, he has neglected to "ring up." If they appear at regular intervals and the chart still shows undue variations, there is undisputable evidence of his incompetence. Laxity or carelessness on the part of the operative, particularly where he has direct charge of the firing, is instantly made apparent. A superintendent may now give directions that temperature readings be made at regular intervals, with the knowledge that his instructions will be carried out.

The value of the time punch is apparent in any plant where accurate temperature control forms a part of routine processes.

GAS-GENERATING APPARATUS

should be securely wired in place and given a coat of paraffine. Sulphuric acid can be used very satisfactorily but it must be greatly diluted to prevent crystallization of ferrous sulphate. The extent of dilution is dependent on the minimum temperature to which the apparatus will be subjected. If this temperature is 10 deg. the acid should not be stronger than 1:14. If 20 deg. is the minimum, the dilution is 1:11. Hydrochloric acid can be used diluted 1:1 or 1:2.

ADVANTAGES OF THE APPARATUS

When in operation, fresh acid drips down upon the iron sulphide until gas is generated at a rate greater than the demand. The level in *C* then drops and that in *E* rises, the increased pressure quickly shutting off the acid supply. No new acid will be admitted until the former supply, working on the Kipp principle, is unable to generate the required amount of gas. Because of the great surface of iron sulphide exposed to the action of the acid in this way almost complete neutralization of

Synopsis of Recent Chemical & Metallurgical Literature

Effect on Electrical Porcelain of the Replacement of Free Silica by Alumina and Zirconia.—The March *Journal of the American Ceramic Society* contains a paper by Robert Twells and C. C. Lin on the effect on electrical porcelain of the replacement of free silica by alumina and zirconia. Since it has been suggested that free silica may be detrimental to the mechanical and the dielectric strengths of electric porcelain, a series of sixteen batches was prepared in which various proportions of the free silica were replaced, weight by weight, by alumina, zirconia or combinations of both, and bars and disks, after burning at cone 8½ to 9, or at cone 12, were tested for shrinkage, transverse strength, impact strength, heat resistance, absorption of moisture and dye penetration. The results show that resistance to sudden temperature changes can be greatly improved by substituting zirconia, that the danger of overburning can be greatly decreased by substituting alumina and that the mechanical strength can be increased by substituting either or both; but in the case of dielectric strength no improvement was obtained by substituting for the free silica.

Rock-Drill Steel.—At the winter meeting of the American Institute of Mining and Metallurgical Engineers, an important symposium on Rock-Drill Steel was held. N. B. Hoffman, metallurgist of the Colonial Steel Co., noted that at the present time a large proportion of drill steel produced in America is manufactured into hollow rods. The process consists of first rolling or forging the ingots to suitably sized billets, approximately 4 x 4 x 24 in., which after thorough annealing are taken to drilling machines and a hole drilled through the long axis of the billet. Next one end of the billet is plugged, the cavity filled with a suitable refractory material, after which the other end is likewise plugged and the billets are ready for rolling. After rolling and cropping, the filling material is removed, and the bars are carefully inspected for physical defects. Solid drill steel is rolled direct; the billets are neither annealed nor drilled.

Some brands of hollow drill steel, especially products of foreign manufacture, are produced by a slightly different process, since the billets are pierced and rolled on a mandrel. The process has been observed on several occasions to produce numerous incipient cracks radiating from the hole in the bar, and ultimately producing a point of failure.

In forging the drill from a straight rod, the hammer end is heated to a high heat and upset to form a collar, after which it is allowed to cool. In most cases the strains set up by forging are severe; Mr. Hoffman personally believed after all forging has been finished, it would pay to thoroughly anneal and heat-treat the entire bar before hardening and tempering the point, at least where the drill has heavy duty such as working in deep holes and hard rock.

When hardening tools, especially multipointed bits, the blacksmith will often get one point harder than the other; consequently in use one point will wear down faster than the other, thus causing the drill to strike an uneven blow. Such things as these make for failures which cannot fairly be blamed upon the steel maker. What is needed today is a drill steel which will withstand impact and at the same time retain a sharp cutting edge—that is, a steel with a tough stiff body, and a point, when forged and hardened, that will be both hard and tough. A large number of tools of like character and the nature of whose work requires similar properties are now being made of alloy steels and used in the industries, to a very great extent displacing ordinary carbon steels, for instance a vanadium steel with a carbon content of 0.75 to 0.85 per cent, manganese 0.25 to 0.35, phosphorus under 0.020, sulphur under 0.030 and

vanadium 0.18 to 0.23, which has proved eminently satisfactory as a chisel steel. A steel of this type properly manufactured will be far superior to the ordinary carbon steels, while at the same time is one whose price range should not prove prohibitive.

Much of the cutting efficiency of a drill depends upon proper heat-treatment, and many drills are broken from being quenched at too high a heat, while others quenched at too low a heat do not harden properly and consequently dull quickly, but the driller, trying to get some duty from the dull bit, often breaks it due to the lack of the cushioning effect of slight penetration into the rock at each blow.

This heat range in the ordinary carbon drills is confined to rather narrow limits. The vanadium steel taken as an illustration has a far greater safe hardening and forging range, making it more nearly foolproof. It will harden nicely at 1,440 deg. F. but will also harden well and satisfactorily at 1,550 deg. F. retaining its quality of hardness and toughness in either case.

Influence of Manganese on the Tensile Properties of Malleable Iron.—The influence of manganese on the tensile strength and elongation of malleable iron has not been well defined; the general belief has been that 0.4 per cent manganese would be a maximum content for a good malleable iron. Dr. E. Leuenberger was studied this problem experimentally and describes the results of his work in the March 3 issue of *Stahl und Eisen*.* His samples were white iron

TABLE I.

Sample	Mn	C	Si	P	S

FIG. 1. INFLUENCE OF MANGANESE ON TENSILE STRENGTH AND ELONGATION OF MALLEABLE IRON

(1 kg./sq.mm. = 1,422.3 lb./sq.in.)

Curves I and Ia heating at 980 deg. C. for 95 hr.

Curves II and IIa heating at 980 deg. C. for 130 hr.

Curves III and IIIa heating at 980 deg. C. for 260 hr.

averaging 2.89 per cent carbon, 0.41 per cent silicon, 0.076 per cent phosphorus and 0.041 per cent sulphur, to which be added varying quantities of manganese in the form of a 50 per cent ferromanganese.

Twelve different analyses with manganese content varying from 0.13 to 1.74 per cent as noted in Table I were heated to 980 deg. C. in an oil-fired furnace for 95, 130 and 260 hours and tested in tension.

The test pieces were cylindrical bars 12 mm. in diameter. Six tests were made in each experiment and the resultant average was accepted as correct. These results are plotted

*"Einfluss des Mangans auf die Festigkeitseigenschaften des Schmiedbaren Gusses," *Stahl und Eisen*, March 3, 1921; p. 285.

in the accompanying figure in which the curves I and Ia, II and IIa, III and IIIa represent respectively the tensile strength and elongation of the samples heated for 95, 130 or 260 hours.

The conclusions derived are: (1) Manganese much above 0.4 per cent is permissible. (2) The tensile strength increases with increased percentages of manganese. (3) Elongation is not affected appreciably by increasing the manganese content up to about 1 per cent, but decreases with higher percentages. (4) The tensile strength decreases when the time of heating increases. (5) The elongation increases with the time of heating. (6) The longer the time of heating the higher the percentage of manganese needed for a given elongation.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Feeding Device for Sulphur Burners.—Referring to the figure, 11 designates the revolving drum of a sulphur burner having a frusto-conical end 12 into which the feeding device projects. The feeding device comprises a hollow body 13 carrying a supply hopper 14 and a feed screw 15. A spout 16 is provided at the discharge end of the body 13 and projects a short distance into the burner but not beyond the frusto-conical end 12. The spout comprises a cylindrical body, 17 having at one end a finished portion 18 which fits accurately within the body 13. Approximately two-thirds of the length of the projecting portion of the spout is cut away above the horizontal diameter, as indicated at 19, so that the discharge

end of the spout is an open trough. This spout is considerably shorter than the spouts heretofore used so that it projects only a comparatively short distance into the burner. The open discharge end offers no resistance to the escape of sulphur so that the sulphur, which is advanced by the feed screw, does not linger in the spout. The fact that the spout is open and exposes the sulphur to the heat of the burner is compensated for by the reduced length so that the sulphur melts very little, if at all, in the spout. The unrestricted opening allows any masses of partly melted sulphur to escape without blocking the spout. The sulphur is fed through a spout according to this invention in a substantially continuous and uniform manner and with much less power expenditure than heretofore. (1,370,627; FRED B. CHAPPELL, of Glens Falls, N. Y., assignor of one-half to Glens Falls Machine Works; March 8, 1921.)

Vanadium Catalyst for Oxidation of Sulphur Dioxide.—A catalyst which effects conversion of sulphur dioxide and oxygen into sulphur trioxide with an efficiency of 96 per cent is obtained by distributing a vanadium compound on a very finely divided carrier not exceeding 60 microns in diameter. Pumice, kieselguhr, precipitated silicic acid, stannic oxide or stannic hydroxide may be used. The following method of preparation is given as an example: Mix 316 parts of kieselguhr (either as it occurs in nature or after trituration) which may previously have been heated to a red heat, with an aqueous solution of 50 parts ammonium vanadate and 56 parts of potassium hydrate; thereupon evaporate off so much of the water that the remainder can be formed into granules; place this result

in a furnace and heat at 480 deg. C. with gas containing sulphur dioxide and oxygen (such as can be obtained from a pyrites burner) and then, if desired, continue the heating for some time in a current of air; the product of this operation is a catalytic agent which is ready for use. (1,371,004; FRANZ SLAMA and HANS WOLT, of Ludwigshafen-on-the-Rhine, Germany, assignors to General Chemical Co.; March 8, 1921.)

Washing Vulcanized Fiber.—Vulcanized fiber made by treating paper with zinc chloride solution is washed free from zinc chloride in solutions of diminishing concentrations until pure water is reached. It requires three to four weeks to wash fiber $\frac{1}{8}$ in. thick. Such a lengthy process is necessary to prevent blistering and at the same time the economical recovery of the zinc chloride is made possible. The danger of blistering is minimized and the time required for washing is considerably reduced by the use of a process devised by OSCAR LINDER, of Chicago, Ill. The fiber is immersed in a zinc chloride solution in the cathode compartment of an electrolytic cell provided with a diaphragm. During electrolysis zinc separates at the cathode and chlorine at the anode so that the strength of the electrolyte decreases gradually and at a uniform rate. The fiber is not connected to the cathode in any way, but is simply placed in the electrolyte so that the removal of the zinc chloride from the fiber is due to direct diffusion of the salt into the surrounding solvent. (1,371,698 and 1,371,699; assigned to Western Electric Co.; March 15, 1921.)

Removing Tar From Pyroligneous Liquids.—The pyroligneous liquors obtained by the distillation of wood are always highly colored due to the presence of tars. Calcium and sodium acetates made from these liquors also contain these tars, which must be destroyed by roasting. The tar can, however, be removed from the liquors before preparing the acetates by using a solvent which is non-miscible with water such as cresol. In making the extraction, EMILE A. BARBET, of Paris, France, suggests the use of a quartz- or coke-filled tower, the pyroligneous liquor being introduced at the top of the tower, and the cresol near the bottom. The tarry cresol which rises to the top is drawn off and distilled to recover the cresol. The decolorized liquor which is drawn off at the bottom of the tower is practically free from tar. The process may also be applied in other industries. (1,371,460 and 1,371,461; March 15, 1921.)

Electrodeposition of Nickel.—Nickel plating with the customary solution of nickel ammonium sulphate is a comparatively slow process, due to the fact that only a 7 per cent solution can be obtained. It has been proposed to use a concentrated solution of nickel sulphate as the electrolyte or plating bath of a nickel-plating electrolytic cell, as it is possible to obtain a 37 per cent solution of this salt, and consequently with such a bath it is possible to impress a current on the cell sufficiently high to plate the nickel out of the bath onto the cathode about five times as fast as is the case when a concentrated solution of nickel ammonium sulphate is used for the electrolyte. However, in cells heretofore used in which a concentrated solution of nickel sulphate is employed as the plating bath, the latter quickly becomes acid. This is due to the fact that in the operation of such cells the nickel dissociated or separated from the nickel sulphate is plated on or taken up by the cathode more rapidly than it is replaced by nickel from the anode, or in other words, more rapidly than the nickel from the anode combines with the SO_4 dissociated from the nickel sulphate by the electric current. Consequently, the excess of SO_4 combines with hydrogen dissociated from the water in the solution by the electric current, to form sulphuric acid. The amount of sulphuric acid so formed continually increases and as this acid acts to dissolve the nickel deposited or plated on the cathode, the efficiency of such cells is soon lost. Moreover, the plating baths of such cells soon become dirty and scum rapidly accumulates on the surface. THOMAS A. EDISON, of Llewellyn Park, West Orange, N. J., maintains the neutrality and composition of a concentrated nickel sulphate bath by circulating it rapidly and continuously through a filter press containing porous cakes of nickel hydroxide. (1,371,414; March 15, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Plans for Chicago Meeting, A.S.M.E.

The 1921 spring meeting of the American Society of Mechanical Engineers is to be held in Chicago, May 23 to 26, at the Congress Hotel.

Well-developed programs will be presented by the professional divisions of the society devoted to Forest Products, Fuels, Machine Shop, Management, Material Handling, Power, and Railroad, and a specially important session will be devoted to Training for Industries. The Chicago committee, jointly with the Western Society of Engineers, is preparing a session on "Chicago as the Rail-Water Gateway."

Visits to a number of points of engineering interest in Chicago will be arranged. Special attention is being given to the correlation of plant visits with the technical sessions.

En route to the meeting, the society, jointly with the Society of Automotive Engineers, will stop at McCook Field on Saturday, May 21, for an inspection of the facilities of the field. On May 27 and 28, the Friday and Saturday following the meeting, a joint excursion with the Army Ordnance Association will proceed to Rock Island Arsenal, where the Ordnance Division will present papers and enjoy an inspection of the plant. Saturday will be devoted to a handicap golf tournament on the Rock Island links.

Government Kelp Products Plant to Be Sold

The kelp products plant of the Bureau of Soils at Sumnerland, Cal., must be sold, under the provisions of the agricultural appropriation bill passed by the last session of Congress. This plant, which is now operating for the production of bleaching carbon, potash salts and iodine, has a capacity of about 100 tons of wet kelp per day. From this it is estimated there can be produced 1,500 lb. of bleached carbon and 2 tons of potash salts daily.

The officials of the Bureau of Soils had hoped to continue the experimental operation of the plant for another year, as by that time they felt certain that it would be generally admitted that the operation was a demonstrated commercial success. However, Congress deemed otherwise and it is now necessary to dispose of the plant as soon after the first of July as a purchaser can be secured. The bureau states that it will make very favorable terms for disposal of the property if it could be assured that the plant will be operated for a sufficient time to demonstrate its possibilities thoroughly. In fact there appears to be more interest in securing a guarantee of operation to complete the experimentation now under way than in realizing any large sum from the sale of the property.

Muscle Shoals Work Stops

Practically all of the work at Muscle Shoals has been stopped. Enough of the money already appropriated for the Wilson dam has been retained to provide for the maintenance of the unfinished project until August, 1922, which is regarded as the earliest time at which new funds are likely to be made available. Enough money also has been withheld to provide for an investigation of the rock beneath the south abutment of the dam as there have been some evidences of instability at that point.

To Examine Georgia Mineral Deposits

The Bureau of Mines is co-operating with the Central of Georgia R.R. in an examination of the clay, feldspar, graphite and bauxite deposits tributary to that railroad. The Bureau of Mines is represented by R. T. Stull, superintendent of its ceramic station at Columbus, Ohio, and by W. M. Weigel, its mineral technologist attached to its Southern experiment station.

Entertainment for Mme. Curie

As Mme. Curie is expected to be but a very short time in New York City, and as it would be impossible for her to attend functions given by any of the individual societies, a luncheon will be given in her honor by the associated chemical societies at the Waldorf-Astoria, on Tuesday, May 17, at 12:30 p.m. Price per cover is \$5. Brief addresses will be made by representatives of each of the chemical societies.

The following gentlemen comprise the committee on arrangements: Chairman, Dr. Edgar F. Smith, American Chemical Society; vice-chairman, Dr. W. S. Landis, American Electrochemical Society; Dr. S. R. Church, Society of Chemical Industry; Dr. George F. Kunz, Société de Chimie Industrielle; secretary-treasurer, Dr. J. E. Zanetti, Chemists' Club of New York City.

Other committees appointed in connection with the luncheon are:

In charge of arrangements with the Waldorf-Astoria Hotel—Dr. George F. Kunz.

Seating—S. A. Tucker, chairman; H. B. Coho, C. A. Doremus, R. H. McKee, J. M. Matthews.

Speakers—Charles Baskerville, chairman; Colin G. Fink.

Program, invitations, music and flowers—Ellwood Hendrick, H. R. Moody, Reston Stevenson.

The following have been appointed to represent their respective societies on the entertainment committee for the entire duration of Mme. Curie's visit:

American Chemical Society—Leo H. Baekeland, Yonkers, N. Y.; Marston T. Bogert, Columbia University, New York City; Prof. J. Enrique Zanetti, Columbia University, New York City; R. B. Moore, U. S. Bureau of Mines, Washington, D. C.; Wilder D. Bancroft, 7 East Ave., Ithaca, N. Y.; Charles F. Chandler, Columbia University, New York City; Charles L. Parsons, 1709 G St., Washington, D. C.; Charles H. Herty, 1 Madison Ave., New York City; W. H. Nichols, 61 Broadway, New York City; Ira Remsen, Johns Hopkins University, Baltimore, Md.; T. W. Richards, Gibbs Memorial Laboratory, Frisbie Place, Cambridge, Mass.; W. A. Noyes, University of Illinois, Urbana, Ill.; S. C. Lind, U. S. Bureau of Mines, Golden, Col.

New York Academy of Sciences—George F. Kunz, chairman; Edward L. Thorndike, Ralph W. Tower, F. A. Lucas, William J. Gies.

American Electrochemical Society—W. S. Landis, president; Colin G. Fink, J. W. Richards, H. B. Coho, E. P. Matthewson.

Society of Chemical Industry—H. G. Carroll, Prof. Ralph H. McKee, Charles H. Herty; S. R. Church, chairman; Allen Rogers, secretary, ex-officio.

Société de Chimie Industrielle—Leo H. Baekeland, Marston Taylor Bogert, Charles A. Doremus, George F. Kunz, chairman; J. Enrique Zanetti.

New York Electrical Society—W. N. Dickinson, president; T. Commerford Martin, C. O. Mailloux, A. L. Doremus, George H. Guy, secretary.

Cooper Union Chemical Society—Prof. Henry C. Enders, George Felder, president.

Following is the text of the appeal by the Marie Curie Radium Fund, which has the task of raising money with which to purchase a gram of radium to present to Mme. Curie in the name of the women of America:

"Women of America are raising a fund of \$100,000 with which to buy a gram of radium for Mme. Curie, who has none with which to continue her research work. It is the one thing most desired by this great scientist. You may aid this fund by subscribing in the name of a woman. Make your check payable to the Marie Curie Radium Fund and send it to the Equitable Trust Co., 37 Wall St."

Chemical Warfare Service Dinner

That the Chemical Warfare Service can rely in the future on general support both within and without the Army became very evident at its third annual dinner held in Washington, April 16. Much significance is attached to the remarks at the dinner of E. J. Wainwright, Assistant Secretary of War, whose warm support of the service hardly would have been forthcoming were it not the attitude of the Administration. The speeches made at the dinner have aroused much comment, particularly in military circles. The Rip Van Winkles in the Army who have been anti-C.W.S. show signs of revising their views with respect to chemical warfare.

The toastmaster at the dinner was Charles H. Herty, editor of the *Journal of Industrial and Engineering Chemistry*. In introducing General Fries he told of the great interest which the 15,000 chemists of the United States have taken in chemical warfare since its introduction into the World War and the very general desire among these chemists to have the public generally awake to the possibilities of this new weapon and to be reliably informed as to all phases of its use.

ADDRESS OF GENERAL FRIES

General Fries in the course of his address declared that he believes in publicity. Were a screen of secrecy drawn across the work of the service, he thinks it would have an adverse affect upon the support given a new activity concerning which there is a great deal of misinformation afloat. General Fries told those assembled at the dinner how the toxic smoke-candle has revolutionized cloud-gas practice and how liquid gas has been improved until it truly is the "dew of death." The battlefield of the future, he declared, never will be free of gas. He analyzed the great advantage which the United States enjoys in having the raw materials needed to make these gases and a great industrial machine which can be diverted to the making of gases in time of war, as well as having the trained personnel which would be required for that service. In concluding his remarks he said:

"The Chemical Warfare Service will guarantee to keep the United States in the very forefront of chemical warfare investigation, development, production and training for just 2 per cent of the Army appropriation, and if the Navy desires it, we can do the same for it for about 1 per cent of the Navy appropriation. With 2 per cent of the Army appropriation we will manufacture all masks needed in peace, including a suitable reserve. We will keep in con-

dition a plant that in time of war will produce masks as fast as men can be mobilized and in addition keep them equipped in the field. We will keep in readiness plants for the manufacture of gases and for the filling of gas shells, bombs and other containers on a scale to meet the needs of any war. We will be able to lead the world in research and development, and we believe that with that 2 per cent we could do as much to guarantee success in war as 25 per cent spent for any other purpose."

PRESIDENT'S PHYSICIAN INTERESTED IN C.W.S.

Brigadier-General Charles E. Sawyer, recently designated by the President to be his personal physician, who was the second speaker on the program, revealed to official Washington that he is an orator and that he has done some sound thinking on public questions. He told of his own interest in chemistry and declared that physicians should use more chemistry in their efforts to diagnose diseases. He stated that he had been impressed particularly with the good which would come in peace time from the research and other activities of the Chemical Warfare Service.

AIR SERVICE RELIES ON GAS

That the Air Service of the Army is relying chiefly upon gas for its war-time effectiveness was indicated by the talk of Brigadier-General William Mitchell, assistant to the chief of the Air Service. He pointed to the vulnerability of New York, where millions of people live within an area of a few square miles. If an enemy were able to get one airplane over the city once in eight days so as to drop two tons of tear gas, it would be necessary for every person in an area of 100 square miles to wear gas masks continuously. If one bombardment squadron, he said, were able to force its way over the New York area once in eight days, it would be possible to drop 70 tons of mustard gas, which then would make it necessary for the entire populace to take further steps to protect itself against that gas. Only two bombing squadrons would have to pass over the New York area once every eight days to drop 200 tons of phosgene, which would make the entire city untenable.

H. C. Parmelee, Editor of *CHEMICAL & METALLURGICAL ENGINEERING*, advocated adequate financial support for C.W.S. by Congress.

GAS WARFARE BY THE NAVY

Following Mr. Parmelee's remarks Rear Admiral W. S. Smith, of the Naval Consulting Board, was introduced. He declared that the Navy is entertaining no delusions as to

CHEMICAL WARFARE SERVICE DINNER, WASHINGTON, D. C., APRIL 16, 1921

the possibilities of gas and that it may be taken for granted that the Navy will be found prepared in that particular. He stated that he favors allotments from the naval appropriations to the Chemical Warfare Service so that it may manufacture the gas needed by the Navy. He said that those doubting the effective use of gas bombs dropped by airplanes against battleships are influenced by the fact that hits seldom are recorded. He admitted that may be the case when a few bombs are dropped at a target, but it would not be the case when a large fleet of airplanes dropped hundreds of bombs simultaneously. Ships must be made gas-proof, he declared.

WILL BE READY FOR NEXT WAR, SAYS WAINWRIGHT

In addition to his remarks supporting the Chemical Warfare Service, Assistant Secretary of War Wainwright declared with emphasis that the United States will be ready for the next war, whether that war be a conflict with a single nation or any combination of nations. He is anxious to have the Army maintain sufficient supplies to enable it to make war without having to draft into service nearly all the productive power of the country's manufacturing plants. He also referred to the necessity of equipping plants so as to make them readily convertible to war needs.

DR. BANCROFT WOULD INTEREST ALL CHEMISTS IN CHEMICAL MEANS OF WAGING WAR

Dr. W. D. Bancroft pointed out the necessity of keeping the chemists of the country interested to the point that they will have in mind at all times the improvement of chemical means of making war. He stressed the point that every man in the military service in the future must be equipped with a certain amount of knowledge as to gas. He made the point that research alone is not enough. Military tactics must be developed and essential training of military personnel must not be overlooked. The mask particularly is subject to great development. No real fighting mask has been developed as yet, he declared.

CONGRESSMEN SPEAK ON PREPAREDNESS

Following the set speeches, Representative Frank W. Mondell of Wyoming, the Republican floor leader, and Representative Julius Kahn, the chairman of the Committee on Military Affairs, were invited to talk. Mr. Mondell emphasized the need for economy in public expenditures, but referred to a proper degree of military preparedness as insurance on which the nation must pay the premium. The development of a new weapon in warfare must not be disregarded, he declared. If other nations should pretend to abandon the use of gas in war, he ventured the assertion that it would be because they are afraid of our prowess in that direction.

Representative Kahn takes no stock in the assumption that wars are things of the past. He stated that it has been his constant effort throughout his public career to strive for a high degree of military preparedness in the United States. Had there been more preparedness before this war, the nation would be much better off today, he asserted. Had it been possible in recent years to secure an annual investment of \$50,000,000 for preparedness measures, the nation would be the gainer by an untold amount today and the very war itself might have been averted. As it is, \$25,000,000,000 was expended in the World War. Thus in a few short months enough was expended to make annual payments of \$50,000,000 for more than four hundred years. He was particular to call attention to the fact that the cost in money represents only the replaceable part of our loss. The lives that were sacrificed and the suffering that was endured, he declared, are losses which head the list in our calculation. He said the Chemical Warfare Service should be given the \$7,000,000 appropriation for which it had asked.

The dinner and the program of speeches were voted by all in attendance to have combined to make an evening long to be remembered. The committee which had charge of the arrangements consisted of Lieutenant-Colonel H. L. Gilchrist, Major R. F. Maddux, R. S. McBride, W. F. Keohan and Dr. A. W. Shaw.

Corrosion and Its Prevention

The program of the Connecticut Valley Section of the A.C.S. calls for one joint meeting yearly with the Hartford Branch of the American Society of Mechanical Engineers. This meeting was held Monday, April 11, following a dinner at the City Club of Hartford.

A paper on "Corrosion and Its Prevention" was read by W. T. Becker of E. F. Houghton & Co., and Dr. A. S. Cushman of the Institute of Industrial Research gave a talk on the fundamental causes of corrosion, with particular reference to the iron and steel industries.

Mr. Becker said that the mechanical engineer was concerned with the temporary protection of iron or steel surfaces against corrosion. After the article in question had reached its destination and been installed the problem of rust prevention ceased to be of interest to him. After dwelling briefly on the electrolytic theory of corrosion he went on to speak of the importance of proper selection of steel for the particular purpose in view. By selecting a steel having the highest possible drawing temperature which will possess the desired properties there results a product in which the steel is less likely to be strained and consequently less likely to develop electropositive spots resulting in rapid corrosion. He listed the practical methods of rust prevention as (1) the use of inhibiting agents (generally, however, in conjunction with painting), (2) painting, (3) covering with a film of oxide, (4) covering with some other metal, zinc, copper or tin in practice, and (5) covering with a non-drying coating as greases or slushes.

Small machine parts, he said, must nearly always be protected by means of the last class of protective agents, for the coating must be readily removed. A great deal of research has been carried out with regard to the development of proper slushing compounds and many good ones have been developed. The two sources of trouble in this class of materials are found to be checking or cracking if the object is cooled too much, and liquefaction of the grease if the object is warmed. Shipments to the tropics demand a different sort of slushing compound than do shipments in colder regions. A very good test for the efficiency of such a grease consists in coating a test-piece in the ordinary way and then hanging it in fumes of hydrochloric acid. If the film of grease is not perfect, it will be quickly apparent. Another good test consists in coating a test-piece with the grease, hanging it in 5 per cent salt solution for twenty-four hours and again coating and immersing until the grease fails. The paper used for wrapping small parts is frequently a source of corrosion. It should contain neither acid nor sulphates.

Dr. Cushman spoke very interestingly of his early work in the field of corrosion. He described the origin of the investigation as due to complaints of farmers in the Middle West about the deterioration of fence wire and told of his earlier experiments leading up to his electrolytic theory now universally accepted. Some slides which he showed made up of wire nails in gelatine containing phenolphthalein and potassium ferricyanide brought out the positive and negative portions very vividly, and one in particular showed the presence of a field of force about a spot in the surface of a bit of steel wire. The lines of force showed up very clearly in the gelatine and should be sufficient to convince any skeptics of the validity of the electrolytic theory of corrosion.

He went on to point out the importance of many recent discoveries in the "higher physics and higher chemistry," as he called them, to practical industrial problems, but he felt that much more knowledge of the fundamental properties of atom and molecule was necessary before the problem of preventing corrosion could be solved.

The Underwood Typewriter Co. allowed the visitors to inspect its factory. A large number of members availed themselves of the opportunity.

Navy to Use C.W.S. Masks

The gas mask developed by the Chemical Warfare Service has been adopted tentatively for use by the Navy.

Last of Government Surplus Brass Sold

All the remaining surplus of brass cartridge cases has been sold by the War Department. The bulk of this surplus brass recently was sold to the Chase Companies, Inc., the Scovill Manufacturing Co. and the Bridgeport Brass Co. The remainder has been allocated as follows: Western Cartridge Co., East Alton, Ill., 2,074,554 lb.; American Copper Products Corporation, Bay Way, N. J., 2,000,000 lb.; Baltimore Tube Co., Baltimore, Md., 500,000 lb.; Wheeler Condenser & Engineering Co., Carteret, N. J., 1,746,812 lb.; Seymour Manufacturing Co., Seymour, Conn., 2,009,306 lb.; Keeler Brass Co., Grand Rapids, Mich., 761,800 lb.; British American Metals Co., Inc., Plainfield, N. J., 2,000,000 lb.; Ansonia Foundry Co., Ansonia, Conn., 1,500,000 lb.; Standard Underground Cable Co., Pittsburgh, Pa., 1,553,045 lb.

Chicago Chemists Club Party

The Chicago Chemists Club gave a party in headquarters, 315 Plymouth Court, on Friday evening, April 15. It was a social occasion or ladies' night in honor of the inauguration of the new president, Otto Eisenschiml. The evening's program was devoted entirely to entertainment. After dinner an informal reception was held in the club lounge for Mr. and Mrs. Hoskins and Mr. and Mrs. Eisenschiml, followed by dancing and a musical program. Later in the evening a smelling contest was held where eighteen unknown substances were offered to the ladies for identification and twenty-four difficult odors were tested out by the men. The attendance of members and guests broke all previous records.

Navy Interest in Chemical Warfare Is Intense

The Navy is making no effort to conceal its very active interest in the experimental and research work being done by the Chemical Warfare Service. The General Board of the Navy, headed by Rear Admiral W. L. Rodgers, recently has spent considerable time familiarizing itself with the work being done at Edgewood.

The contrast between the interest displayed by high naval officers, as compared with that shown by the General Staff of the Army, is a cause of comment. A change in the policy of the General Staff, however, may take place when the appointee of the new administration takes over the direction of its work.

Plans for Recovery of Wastes at the Holland-St. Louis Sugar Plant, Decatur, Ind.

Following months of scientific research by engineers in which officials of the State Department of Conservation cooperated with officials of the Holland-St. Louis Sugar Co., of Decatur, Ind., and the State Board of Health, Richard Lieber, Director of Conservation, has announced that a plan has been adopted by which it is expected to free St. Mary's River from pollution caused from vegetable matter and refuse from the sugar refinery.

The plan, which has the approval of the Conservation Department, heads of the engineering department of Purdue University, the State Board of Health and the Holland-St. Louis Co., will involve an expenditure by the latter of approximately \$104,000 for the erection of a plant to handle and dispose of the refuse in such a way as to reclaim the byproducts. This plan, engineers claim, will recover potash for use as fertilizer, will increase the sugar yield, and such wastes as eventually reach the river will have been so purified that all contaminating influences are lost.

The wastes from the plant may be divided as follows: (1) Beet-carrying and wash water, 2,000,000 gal. per day. (2) Diffusion battery and pulp press water, 200,000 gal. per day. (3) Lime press cake, 37 tons as a solid cake containing 50 per cent moisture, or 150,000 gal. when diluted with water to make a liquid that will readily flow. (4) Steffens house wastes, 200,000 gal.

No. 1 waste contains beet tails, beet tops, earth and beet roots, but very little soluble organic matter. Its biolog-

ical oxygen demand is zero. It is therefore planned to keep this liquid separate from the other wastes, which can readily be accomplished, pass it through fine screens and discharge it continuously into the river.

DIFFUSION BATTERY WATER RE-USED

No. 2 waste contains much organic matter in solution and also considerable in suspension. Very careful consideration was given to treatment of these wastes and methods were actually devised for coagulating and settling them so that the supernatant liquid could be discharged into a storage lagoon and from there permitted to flow in the river at a rate more or less proportional to the stream flow, so that the stream at no time would be excessively polluted. However, there was finally worked out with the assistance of the company superintendent a method for re-using these wastes. This method is not altogether new, but it is novel in that the wastes will all be recirculated into the process. Treatment comprises liming and carbonating in a manner similar to the treatment applied to the main volume of juice in the plant and then re-using the liquid in the diffusion batteries. The purpose of the liming and carbonating process is to precipitate out non-sugars, which are then filtered off, leaving as a waste a lime press cake which, however, will not greatly increase the volume of lime press cake already produced.

LIME PRESS CAKE

The lime press cake may be handled either as a relatively solid cake or as a rather thick liquid. If handled as a cake, it would be removed from the factory on a small narrow-gauge railroad and dumped at some convenient point where dumping grounds are available. This method, while perhaps the cheapest available, is objectionable, inasmuch as it involves considerable labor. Labor is always hard to get at beet sugar plants because the "campaign" lasts for only 100 days. Accordingly the company favored mixing the cake with water (which water incidentally is used for assisting in the cleaning of the presses) and pumping it to lagoons, where it will be stored until the volume of flow in the river is sufficient to afford ample dilution. It is estimated that a storage capacity sufficient to hold 25 days' production of the liquid lime cake will tide over any period of insufficient dilution in the river that is likely to occur.

POTASH RECOVERED FROM STEFFENS WASTE

The fourth waste is exceedingly strong in organic matter, though low in suspended solids. It results from the process used to recover additional quantities of sugar from the molasses after the first direct recoveries have been made. This waste will be evaporated to dryness in multiple effect evaporators and the final sirup will be ignited for the recovery of potash. It is probable, however, that the ignition process will not be conducted at the plant, but the sirup itself will be barreled and sent to fertilizer works. This process of recovering potash is not new and in fact was used at this plant before. The building in which it was housed burned down in 1918 and owing to the unfavorable market for potash that developed subsequently it was never rebuilt. It is not likely now that the process will pay for itself owing to continued unfavorable potash market. However, when looked upon as a method for treating the wastes, it is reasonably economical.

BIOLOGICAL PROCESSES NOT APPLICABLE

It is to be noted that ordinary methods of sewage treatment involving biological processes are difficult to use in connection with beet sugar wastes for the reason that the campaign runs for only 100 days and it would take any biological process at least several weeks to ripen, during which period most of the damage would have been done in the matter of stream pollution, inasmuch as the campaign is started in October when stream flows are ordinarily low. Another objection to biological processes is that the waste carries so much organic matter that very extensive filter areas are necessary to give the desired capacity. This makes biological processes exceedingly expensive.

Imports and Exports of Chemicals

Imports of chemicals decreased in a very unusual manner during February. Total imports for the month were valued at \$7,434,811, as compared with \$16,460,296 in February of 1920. The total imports of January, 1921, were \$12,221,850. Thus there was a decrease over the corresponding month of last year of more than \$9,000,000, while the decrease from January was nearly \$5,000,000. The figures are those of the Bureau of Foreign and Domestic Commerce.

The decline came largely among the gums—camphor, copal, gambier and shellac. There were slight increases in imports of colors and dyes and in coal-tar products. Outside of the major group some of the imports were as follows:

	Feb., 1920 Pounds	Feb., 1921 Pounds
Iodine	6,975	55,846
Lime, chloride of.....	110,633	257,824
Potash, carbonate of.....	23,263	126,137
Soda, cyanide of.....	996,979	11,023
Arsenic	259,518	564,191

Exports of chemicals also declined sharply. The value of all chemicals exported during February of 1921 was \$5,998,415, as compared with \$13,197,994 in February of 1920 and \$9,420,043 in January of 1921. The decrease applies through each of the major groups as follows:

	Feb., 1920 Value	Feb., 1921 Value
Acids	\$407,564	\$141,455
Dyes and dyestuffs.....	2,461,797	548,420
Extracts for tanning.....	468,711	82,755
Sodas	1,708,544	437,830

Tungsten in 1920

Not since 1902 has the United States produced so small a quantity of tungsten concentrates as in 1920, according to Frank L. Hess, of the United States Geological Survey, Department of the Interior. The Wolf Tongue Mining Co. and the Vasco Mining Co., of Boulder, Col., were the only American tungsten miners. They produced an equivalent of 216 short tons of ferberite ore carrying 60 per cent tungsten trioxide (WO_3).

Tungsten is most used for making high-speed tools for cutting steel, so that the demand for tungsten ore rises and falls with the steel business. In 1920 the steel business was very dull and the demand for tungsten was correspondingly small. At the same time, in spite of the small demand, the imports were rather large for peace times, and consisted in part of very cheap ore from the shallow placers of China. A good deal of the ore was apparently shipped to this country with the expectation that a heavy duty would be imposed on it and that ores in stock would accordingly increase in value. The imports for 1920 were 1,740 long tons of ore, probably averaging 65 per cent or more tungsten trioxide (WO_3) and were equivalent to about 2,111 short tons of concentrates carrying 60 per cent WO_3 . Of this quantity 1,386 short tons of 60 per cent concentrates was shipped from China and most of the rest from South America. Besides the ore 1,997,719 lb. of tungsten and ferrotungsten was imported, equivalent to about 2,250 short tons of 60 per cent ore, and probably more than enough to supply the needs of the high-speed tool industry, so that there was added to the already large stocks in this country somewhat more than the quantity of tungsten represented by the imports of ore.

Exact figures are not at hand, but a large quantity of tungsten ore is in stock in this country, probably more than a three years' supply at the average consumption before the world war.

Armour Research on Nitrides

Prof. Harry McCormack, of the Armour Institute of Technology, spoke before the Chicago Chemists Club on April 12 on "Experiences With a Few Nitrides." Dr. McCormack has been doing research work on nitrides for the past five years, a good deal of his time being devoted to studies with zinc nitrides and aluminum nitrides. While his work on this subject has not been brought to a definite conclusion, a considerable amount of interesting data has been compiled. It is not at all impossible that the manufacture of aluminum nitrides may some day be a commercial process for the fixation of atmospheric nitrogen.

Distillation of Missouri Oaks

The problem of the distillation of Missouri oaks was undertaken in the chemical laboratories of the Missouri School of Mines and Metallurgy to note the yields of products from both the white and black oaks, and to determine the advantage or disadvantage of conducting distillations under reduced pressure. The results of this work were outlined by K. K. Kershner, E. W. Rembert and M. S. Badollet at a meeting of the St. Louis Section of the American Chemical Society, April 8.

The distillations were carried on in a coal-fired, horizontal, cylindrical iron retort, large enough to contain a charge of one-third of a cord of wood. All operations were conducted under good chemical control features and the plant was equipped with adequate condensers and washers. The accompanying table gives the amounts of the various products secured from an average distillation of an 800 lb. charge, running 17 per cent moisture.

DISTILLATION PRODUCTS AND YIELDS

	Normal Pressure		Reduced Pressure	
	White Oak	Black Oak	White Oak	Black Oak
Charcoal, lb.....	200.0	205.0	245.0	251.0
Gas, cu.ft.....	2,910.0	2,785.0		
Pyroligneous acid, lb.....	424.0	414.0	463.0	461.0
Tar-coke, lb.....	1.5	2.0	2.5	2.6
Tar, dissolved, lb.....	14.0	14.4	16.0	20.0
Tar, settled, lb.....	5.4	8.7	10.0	9.9
Acid, as acetic, lb.....	26.7	24.0	30.8	27.7
Acetone, lb.....	1.1	1.1	0.8	0.8
Esters, as methyl acetate, lb.....	1.7	1.3	0.7	1.5
Methanol, lb.....	12.6	15.7	11.3	12.8

The omission of the yield of gas from the reduced pressure distillation is intentional, due to the fact that the suction would occasion an intake of air through every small aperture or leak throughout the entire system.

The greater part of the distillation was conducted under a reduced pressure of 55 to 67 mm. of mercury, a drop to 21 mm. occurring for a short time at the firing point of the charge. The gas ranged from 200 to 500 B.t.u. and gained steadily in amount and heating value as the distillation progressed past the firing point. A general sample of the gas would run about 400 B.t.u. Analysis of gas samples taken every half hour showed that as the distillation progressed there was a drop in carbon dioxide and a gain in unsaturated hydrocarbons, carbon monoxide, methane and hydrogen. There was also a corresponding loss in nitrogen percentage.

About one-third less fuel was required for a reduced pressure distillation as compared with a normal run, although there was a greater tendency for the take-off to become clogged with tar and tar-coke. It was also possible to make a cut containing a higher concentration of desired products in the distillate during a reduced pressure distillation, due to the fact that the greater part of the moisture was removed in the earlier stage of the run.

Obituary

LESTER GRAY FRENCH, prominent in technical journalism and for thirteen years editor and manager of *Mechanical Engineering*, official journal of the American Society of Mechanical Engineers, of which he was assistant secretary, died on April 18 at the French Hospital, New York City, after an operation. Mr. French was born in Keene, N. H., and was graduated from the Massachusetts Institute of Technology in 1891. He began his career as a draughtsman with the Cranston Printing Trust Co. and later was identified with engineering education. In 1897 he became editor-in-chief of *Machinery*, resigning in 1906 to publish technical books. He wrote one of the earliest American treatises on the steam turbine. In 1908 he was made editor of the journal of the American Society of Mechanical Engineers, of which society he was elected a junior in 1899 and a member in 1912. Mr. French was also a member of the Engineers Club of New York.

Personal

JOHN A. BAKER, formerly assistant general superintendent for the Mesta Machine Co. of Pittsburgh, Pa., has been appointed works manager for the Los Angeles plant of the Rich Steel Products Co.

Dr. JAMES BRYANT CONANT, assistant professor of chemistry at Harvard, and Miss Grace Thayer Richards, daughter of Prof. Theodore W. Richards, were married at Cambridge, April 17. The couple intend to travel in Europe during the summer.

JOSÉ ELORRIETA, director of the Forest Service of Vizcaya, Bilbao, Spain, has just completed an extended trip through the United States investigating the forestry of this country. Among other points visited were Chicago and the Forest Products Laboratory at Madison, Wis. He is returning home via Boston.

HAROLD G. MANNING, formerly an assistant examiner in the U. S. Patent Office, and a graduate of the Massachusetts Institute of Technology, has recently opened an office in Waterbury, Conn. Mr. Manning was at one time associated with the law firm of Williams & Pritchard in New York City, and later with the patent department of the Columbia Graphophone Co. of Bridgeport, Conn. While in the Patent Office, he specialized in the examination of electrochemical inventions.

W. C. PETERSON, who for the past twelve years has been associated with the Packard Motor Car Co., in charge of its metallurgical laboratories, has been placed in charge of the metallurgical department of the Atlas Crucible Steel Co.'s mills at Dunkirk, N. Y. Mr. Peterson's work at the Atlas will include research and standardization of the new chromium-molybdenum products which have already been introduced to alloy steel purchasers of the country.

GEORGE B. TROXELL, who has been connected with the Bethlehem Steel Co., Bethlehem, Pa., for the past five years, resigned as assistant superintendent of the electric furnace and crucible departments. He is considering a South American project.

U. C. YOUNG, formerly plant engineer with the Provident Chemical Works of St. Louis, has severed his connection and is now manager of the chemical works of the Calumet Baking Powder Co., Joliet, Ill.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, April 25, 1921.

Trading in heavy chemicals has shown little change during the past week and has been limited to comparatively small lots. Consumers still lack confidence and show no interest beyond their immediate necessities, in spite of offers of material at extremely low prices by holders. Prospective tariff changes are awaited with keen interest and in general enough uncertainty surrounds the chemical industry to warrant the conservative policy that is so manifest.

Manufacturers of chemicals are not discontented over business conditions. Sales cannot be compared with last year at this time, but the demand has shown a marked improvement compared with the first few months of this year. Soda ash is in strong demand for consuming wants. Glass, textile and soap plants are taking this chemical in moderate volume. Solid caustic soda is being well maintained in first hands. Export inquiries from South America are reaching the market quite frequently. Bleaching powder is moving in fair dimensions for domestic consumption. Bichromate of soda has shown a decided improvement, with

small lot sales predominating. Foreign muriate of potash and prussiate of soda have remained fairly steady. Imported caustic potash has attracted a little attention on account of the relatively low prices prevailing. Leading producers, on the other hand, have reduced prices on sal ammoniac, glaubers salt, sulphite of soda and hyposulphite of soda. Arsenic, copper sulphate and other chemicals used for agricultural purposes are not finding an open market. Farmers are not disposed to take much interest in their products when agricultural commodities are selling at the lowest level since the war.

In general, it may be stated that the chemical industry is undergoing a slow development. Slow business usually causes irregularity, but the basic conditions are making for a gradual improvement. The reduction in wage scales and in prices of finished products have been accomplished with very little difficulty.

GENERAL CHEMICALS

Spot bichromate of soda closed firm with most sellers asking as high as 7½c. per lb. Sales were reported for small lots at this figure. The market looked tight, and while it was admitted that a moderate amount of stock is being held by dealers, there is no apparent disposition to release offerings at prevailing prices. Light sales of caustic soda were reported at \$3.65@\$3.70 per 100 lb. ex-store N. Y. It is probable that \$3.60 can be done in some directions, although cheap offerings of standard brands have been well cleared from the market. Producers' prices are unchanged at former levels. Demand did not show any unusual activity so far as resale goods are concerned, although manufacturers did a fair business for prompt and future shipments. Resale light soda ash is scarce and prices are higher. Prominent sellers ask up to \$2.10 for single bags in carload lots on spot. Double bags are not plentiful and are held at \$2.20 per 100 lb. f.a.s. steamer. Barrels are moving at \$2.30@\$2.35. The demand is quite steady. Producers' contracts are unchanged at \$1.72½, basis 48 per cent, in carload lots for single bags f.o.b. works. Imported prussiate of soda has not shown any noticeable strength during the week and the market has been kept unsettled through the keen competition of holders. The range extended from 11½@12c. per lb. during most of the period, but at the close it was reported that 11½c. would probably be accepted by some sellers on a firm bid. Moderate quantities of resale solid sodium sulphide, 60-62 per cent, are being offered by second hands at 5½c. per lb. and some business is reported at this level. The broken variety is quite scarce and is held firmly at 6½c. The War Board has placed nitrite of soda on the list of restricted imports and it is possible that this might force prices up around producers' costs. Stocks around town are known to be quite heavy with offerings for spot material as low as 5½c. per lb. Norwegian nitrite could not be had for less than 10c. per lb. for shipment.

Consumers of arsenic are reported to be well supplied with this chemical at present and the market presented a quiet appearance. Resale lots have reached the market during the week at 7½@8½c. per lb. Leading producers are holding shipments at 8½c. The fact that agricultural material has declined is said to be responsible for the lack of inquiry from manufacturers of insecticides. Spot barium chloride is held at \$60 per ton. The market is still considerably above pre-war figures and buyers are operating on a conservative basis. Imports of magnesium sulphate have been very heavy during the past week, but there was very little change noted in quoted prices. Commercial imported sulphate is quoted at \$1.40 per 100 lb. as against \$2.20 named by domestic makers. Prices on caustic potash are very uncertain in the absence of any demand. Domestic makers are quoting prices far above the spot market. Imported caustic is very weak at 8c. per lb. and resale American material is quoted down to 7@7½c. per lb. Resale prices for formaldehyde range from 13@14½c. per lb., dealers naming about 13½c. Producers are asking 15@15½c., but might consider lower prices on a firm offer. Producers of tin oxide report small sales on the basis of 40c. per lb. Occasional trading in resale lots has gone

through at 39c. Demand has not shown much activity, but offerings are not heavy and the tone appears quite firm.

COAL-TAR PRODUCTS

Trading in intermediates has been entirely without new developments. Prices have been soft in all quarters, with the consuming demand at a very low ebb. A great deal of uncertain feeling that has hung over the market for so long a period is disappearing, however, and the views in producing circles are of a much more optimistic nature, since the intentions of Washington authorities are now more clearly in favor of protection. Conditions in many of the textile mills have shown progressive development. Interest in intermediates and dyestuffs for furs has been fairly active, in view of the business now developing through fur auctions in New York, and *para amidophenol* reflected a steady tendency. The silk mills reported a fair amount of orders from retail quarters. There has been no material change in intermediates, except that distressed lots of *aniline oil* were heard on the market at 18c. per lb. The demand for *beta naphthol* was practically unchanged, although resale material has not been plentiful of late. Prices are quoted at 40@45c. per lb. by makers, while resale lots are held at 32@34c. Prices on *para nitraniline* are still very uncertain, with quotations over a range of 85c.@\$1.05 per lb.

The *naphthalene* market continued dull, with resale material still to be had in sufficient quantity to meet all present requirements. Prices in the resale market for flakes are around 8c. per lb. The refiners of *naphthalene* are asking 8½@9½c. for the flake and 9½@10½c. for the balls, depending on quantity. Business with the fur trade has been fair, but is showing signs of slowing up. *Benzene* producers continue to control supplies and are holding prices firm at former levels, in spite of the lack of interest from consumers. Business, however, is showing some signs of improvement with orders coming in more regularly. There has been very little activity in the market for *aniline salt*. Supplies are available in most quarters and while prices are quotably unchanged at 26@29c. per lb., a firm order would probably induce holders to shade.

The Chicago Market

CHICAGO, April 23, 1921.

There were few developments of noteworthy character in the market for industrial chemicals during the past week. Consumers are still averse to purchasing beyond their immediate needs and business was of the same hand-to-mouth character that has been noted for some time past. The prevailing tone was easy and many products were obtainable at lower prices. *Soda ash* is easier at 2½c. per lb. in small quantities. There are no new developments in *caustic soda*, the market being steady with the offerings light for prompt and nearby delivery. The solid is quoted around \$4.10 per 100 lb. and the ground at \$4.75 in ton lots. *Aluminum sulphate*, iron free, is very quiet, there being little or no demand from the consuming trade. This material is offered on spot at from 3½@4c. per lb., depending upon the quantity. *Ammonium chloride*, white gran., is lower, and is offered in some quarters at 9c. for single barrels. Consumers think this price is still too high and are waiting for further breaks.

Methanol showed no further decline, although the inquiry is light. Second hands are asking 80c. per gal. for the 95 per cent in drums and 85c. for the 97 per cent. There is little or no request for *barium chloride* and the price is unchanged at \$75@\$80 per ton. *Barium peroxide* is also very quiet and is offered at 18c. per lb. There is an ample supply of *carbon tetrachloride* available at 11c. for large drums. Holders show no disposition to shade this price, some factors believing that the market will react soon and that they will be able to obtain higher prices. *Iron sulphate* is in fair demand and is quoted at 1½@2½c., according to the package. Calcined *carbonate of potash*, 80-85 per cent, is easy, and is offered freely at 11c. in cask lots. The continued arrival of cheap foreign material is weakening the market and lower prices are expected. *Caustic potash* is stagnant, with second hands in control of the

market. They are offering 88-92 per cent material of foreign origin at 8@8½c. per lb., while large business would probably bring out even better prices. Resale lots of *bichromate of potash* are available at 14½c. per lb. in casks. *Bichromate of soda* is steadier; 9c. per lb. for spot material seems to be the best offer, while some factors have advanced their ideas to 9½c. Dry powdered *sodium bisulphite* is slowly getting back to normal and is available at 6@6½c., according to the holder. *Sodium bicarbonate* of standard brands is offered at 2½c. per lb. for less than carlots. There are reports from some quarters that a fair volume of business is done at these figures.

Pernanganate of potash is lower, U.S.P. material of domestic manufacture being now available at 39c. per lb. This price is still far from the pre-war level and with the low-priced foreign material coming in lower prices can be expected. C.p. *glycerine* has been reduced by refiners to 16½c. per lb. in large or small drums. This marks the lowest level reached in over ten years and can hardly be expected to go much lower.

In general, there is little change in the list of acids. *Acetic, glacial*, is maintained at 11c. per lb. and the 28 per cent commercial at 2½@3c. per lb. *Hydrochloric*, 18 deg., is steady at 2@3c. per lb. in carboys, price depending upon the quantity. *Sulphuric* is unchanged at \$19@\$20 per ton in tank cars and 2@3c. in carboys. *Nitric* is asked for in small quantities and is quoted in carboys at 8½@9c. per lb.

VEGETABLE OILS

Unusually quiet conditions still prevail in the vegetable oils trade. *Linseed oil* is freely offered at 60c. per gal. in barrels for the raw and 62c. for the boiled. There is little demand from the consuming trade and there is some talk of further reductions. *Corn oil* is in small demand and is offered at 10@11c. per lb. The inquiry for *coconut oil* has improved somewhat, and the price remains unchanged at 10@10½c. per lb.

NAVAL STORES

There were several substantial price advances reported in the local market for naval stores. The leading dealers have advanced the price on *spirits of turpentine*, which is now generally quoted at 65c. per gal. in barrels. Business in *rosins* is slightly more active, the WG grade now being quoted at \$7.75@\$8 per 280 lb. *Rosin oil* is firm at 55c. per gal. in barrels.

COAL-TAR PRODUCTS

There were no developments to speak of in coal-tar products, and, in general, prices are unchanged. *Benzene* is quiet, the prevailing quotations being 28@31c. per gal. for the 90 per cent, and 30@33c. for the pure. Refined *toluene* is unchanged and an ample supply is available at 33c. per gal. in drums. There is a slight movement of *naphthalene flakes*, with most holders asking 8½@10c., according to the size package.

The Iron and Steel Market

PITTSBURGH, April 22, 1921.

Price readjustment in the steel market is now practically complete, and practically the whole market is now on a uniform basis as between the Steel Corporation and the independents. Prospects are that the market will remain on this equalized and stabilized basis for some time to come, possibly through the summer. The Steel Corporation has no incentive to reduce its new prices, as it has absorbed a great deal since the Industrial Board settlement of March 21, 1919, including the absorption of the wage advance of Feb. 1, 1920, the freight rate advance of Aug. 26, 1920, and the present price reductions, all without reducing wages.

The market is now quotable steady all along the line as follows: Billets, \$37; slabs, \$38; sheet bars and small billets, \$39; forging billets, \$42; rods, \$48; merchant bars, 2.10c.; shapes, 2.20c.; plates, 2.20c.; hoops, 2.75c.; blue annealed sheets, 3.10c.; black sheets, 4c.; galvanized sheets, 5c.; tin plate, \$6.25; plain wire, 3c.; wire nails, \$3.25; standard steel pipe, 62½ per cent basing discount.

New seamless tube prices have been announced by the

National Tube Co., representing a reduction of about \$20 a ton from the Industrial Board schedule. At the same time there is a reversion to the system of quoting discounts from list, the Government price control having started a new system, that of quoting per net ton. Discounts are: 1-in., 56 per cent; 1½-in., 49 per cent; 1½-in., 48 per cent; 1¾-in., 25 per cent; 2 to 2½-in., 17½ per cent; 2¾ to 4-in., 20 per cent; 4½ and 5-in., 7½ per cent, on cold-finished seamless tubes.

MANUFACTURED PRODUCTS

New prices have been made by steel mills or others on various manufactured steel products, and the following prices may now be quoted: Standard railroad spikes, 3.30c.; ½-, ⅞- and 1-in., 3.65c.; 1½-in., 4.25c.; boat and barge spikes, 3.85c.; track bolts, 4.50c.; chain, 6.35c., base, for 1-in. proof coil; button-head structural rivets, 3.50c.; cone-head boiler rivets, 3.60c.; cold-finished steel bars, 3.10c.; cold-rolled strip, 5.50c.

Prices of manufactured steel products in general show larger percentage spreads above the mill prices of the hot-rolled material from which they are made than obtained before the war. Thus, if the disposition of the ultimate consumer to make purchases is to be gaged by the price, which usually is not precisely the case, comparison should be made of the prices of the manufactured products rather than of the mill prices for the intermediate material. For illustration, comparing present prices with average prices in the five years 1909 to 1913 inclusive, bars at 2.10c. are up 58 per cent, while standard railroad spikes at 3.30c. are up 104 per cent.

BUYING LIGHT

New buying in steel products has been very light since the market got on the stabilized and equalized basis. It is understood that the independents gathered up a very fair volume of business as they were withdrawing their extreme prices, as of course they were willing to accept orders if the buyer would act at once. This will probably give the independents a better operation for the next two or three weeks than they have had. Their average rate early in April was about 35 per cent of capacity, against about 32 per cent in March and 30 per cent in February and January.

The Steel Corporation is receiving slightly more business than formerly in releases against suspended orders and in specifications against old contracts, now that it has reduced its prices, as of course the reduction applies to unexecuted obligations. Last week and this the corporation's operations as a whole have averaged about 40 per cent of capacity or a shade less, there having been a continued decline from the rate of 90 per cent shown for January. Corporation operations have probably rounded the turn, and may mount to 50 per cent within a few weeks.

PIG IRON AND COKE

The pig iron market continues to exhibit an almost complete apathy on the part of buyers. Indeed, the only inquiry of any consequence for any grade is a single inquiry for 10,000 tons of basic, for the United Alloy Steel Co., Canton, Ohio, and doubts are entertained whether any considerable tonnage will really be bought at this time against the inquiry. The market remains quotable at prices formerly developed, \$25 for bessemer, foundry and malleable and \$23 for basic, f.o.b. valley furnaces, freight to Pittsburgh being \$1.96. Consumption of merchant iron is at a very low rate and production is at a still lower rate, but there are stocks of considerable magnitude in the aggregate still to be absorbed before the market is equalized as between the buying power of the consumer and the production cost of the merchant furnaces. The furnaces can now have no complaint as to the cost of coke, in this general matter of deflation of costs and selling prices, since recent sales of Connellsville furnace coke at \$3.50 have been followed by some small sales at \$3.30 per net ton at ovens. The high freight rates remain, putting a great burden on furnaces in assembling about four tons of material per ton of pig iron made.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

LITTLE ROCK—The Arkansas Producing & Refining Co., Gazette Bldg., has plans under way for the erection of a new oil refinery in the vicinity of El Dorado, Ark., to have an initial capacity of about 3,000 bbl. The plant will comprise a large tankage system, both for run-down and storage service, with pipe lines extending to the company's wells, about 5 miles distant. The new plant is estimated to cost in excess of \$125,000. The company is capitalized at \$350,000. George A. Sonricker, El Dorado, is engineer for the project.

Connecticut

SOUTH MANCHESTER—The Rogers Paper Mfg. Co. is planning for the rebuilding of the portion of its plant destroyed by fire, April 14, caused by an explosion.

Delaware

WILMINGTON—The Electric Hose & Rubber Co., 12th St., manufacturer of rubber hose, has awarded a contract to John E. Healy & Sons, 707 Tatnall St., for the erection of a 1-story addition, 57 x 90 ft., to be equipped as a pressing department. C. D. Garretson is general manager.

Florida

MIAMI—The Moore Haven Sugar Corp. has awarded a contract to the L. R. Steel Corp., Atlanta, Ga., for extensions and improvements in its mills at Moore Haven. A large part of the plant will be remodeled and considerable machinery installed. The present work is estimated to cost about \$350,000, and will be supplemented by other improvements and additions at a later date to cost a like sum. John C. Grambling is secretary and treasurer.

BUNNELL—The Pidcock-Roberts Co., recently organized, is planning for the development of ocher and sienna properties in this section. It is proposed to install a complete washing plant and other operating machinery. J. N. Pidcock is president, and D. B. Roberts secretary-treasurer and general manager.

Illinois

CHICAGO—The Scientific Oil Co. plans the erection of a \$10,000 building at 1645 South Kilbourne Ave. as addition to existing plant.

Indiana

INDIANAPOLIS—The Henry Furnace & Foundry Co., 915 North Davidson St., has preliminary plans under way for the erection of a new 1- and 2-story plant on Massachusetts Ave., to cost about \$100,000. It is expected to call for bids some time in June.

RUSHVILLE—The Dill Foundry Co. is arranging plans for a 3-story plant addition, 40 x 100 ft., estimated to cost about \$40,000. William Dill is secretary and treasurer.

Louisiana

ST. ROSE—The Petroleum Export & Import Co. has awarded a contract to H. P. Farnsworth, St. Charles St., New Orleans, La., for the erection of a number of new buildings for its oil works. Five buildings will be erected, including a barrel-filling plant, 60 x 250 ft.; canning plant, 60 x 175 ft.; power plant, 40 x 70 ft.; pumping plant, 60 x 90 ft., and boiler plant. The company is a subsidiary of the Carson Oil Co., 29 South La Salle St., Chicago, Ill., of which Edward B. Carson is president.

MARRERO—The J. S. Long Co., manufacturer of soap products, is planning for the rebuilding of the portion of its plant, recently destroyed by fire with loss estimated at about \$100,000 including machinery.

Maryland

HAGERSTOWN—The Maryland Fiber Products Co., recently incorporated with a

capital of \$150,000, is planning the establishment of a local plant for the manufacture of fiber specialties, including boxes containers, etc. Mark H. Landis, manager of the Landis Engineering & Mfg. Co., Ringgold St., Waynesboro, Pa., is head of the new company. Richard G. Stevenson and Thomas M. Cunningham, Hagerstown, are directors.

CUMBERLAND—The Potomac Glass Mfg. Co., is planning for the rebuilding of the portion of its plant, recently damaged by fire.

BALTIMORE—The American Sugar Refining Co., 117 Wall St., New York, is completing plans for two new buildings to be erected at its local refining plant at Woodall and Clement Sts. The structures will comprise a 9-story manufacturing plant, 140 x 320 ft., and 7-story pan house, 80 x 154 ft., both of steel and reinforced concrete. The entire plant is estimated to cost in excess of \$5,000,000.

BALTIMORE—The new paper mill to be erected by the Gwynn's Falls Paper Co., 517 Equitable Bldg., at Gwynn's Falls, will comprise a main 1-story building and a number of smaller structures, estimated to cost about \$250,000 with machinery. The company has recently filed articles of incorporation with a capital of \$600,000. George W. Davis is head. Joseph H. Wallace, 5 Beekman St., New York, is engineer for the project.

Massachusetts

WALTHAM—The O'Hara Waltham Dial Co., Rumford Ave., has broken ground for the erection of the proposed 1-story addition to its watch dial manufacturing plant, 50 x 65 ft., to cost about \$15,000. L. J. Geoffrion, 12 Howard St., has the building contract. Eliot O'Hara is head.

New Jersey

NEWARK—The Paragon Tannery Co., a new organization, has leased a portion of the plant of the Universal Caster & Foundry Co., 106-26 Adams St., near Ferry St., totaling about 35,000 sq. ft. of space, for the establishment of a new tanning plant for shoe and glove leather. Possession will be taken at once and it is proposed to have the plant ready for service at an early date.

JERSEY CITY—The Richard Chemical Co., Warren St., has taken bids for the construction of a 4-story brick addition, 50 x 54 ft., estimated to cost close to \$40,000.

New York

NORTH TONAWANDA—The Earl R. Maltby Co., Ellicott Sq., Buffalo, has awarded a contract to Morris & Allen, Prudential Bldg., Buffalo, for the erection of the first unit of its proposed new plant at North Tonawanda for the manufacture of paper roofing products. The factory will be 1-story, 100 x 130 ft.; construction will be inaugurated at once.

BUFFALO—The Climax Compression Tube Co. of New York, Inc., 200 Cherry St., manufacturer of rubber tubes, etc., is planning the establishment of a new branch plant in this section. Negotiations are under way for the purchase of an existing works, to be equipped immediately for production. To finance the proposed expansion, the company has arranged for a stock issue of \$1,000,000, and a large portion of the proceeds will be used for machinery and equipment. A. L. Case is chairman of the board.

Michigan

DETROIT—The Jeffrey-DeWitt Co., Butler Ave., manufacturer of spark plug porcelain, laboratory porcelain products, etc., is completing plans for the erection of its proposed new 5-story and basement plant at Hamtramck, to be reinforced concrete and estimated to cost about \$200,000 with machinery.

DETROIT—The General Spring & Wire Co., 1930 Marston Ave., will take bids about the middle of May for the erection of a new 1-story plant, 200 x 250 ft., to cost about \$175,000 with equipment. A power house will also be constructed. C. L. Clerk is secretary, Edward D. Shank,

38 South Dearborn St., Chicago, Ill., is architect.

Ohio

NORWALK—The Pioneer Rubber Co. has completed plans for the erection of its proposed new 2-story and basement plant, 40 x 80 ft., estimated to cost about \$30,000. B. G. Smith is head.

TOLEDO—The Standard Oil Co. has completed the erection of its new Bay Shore refinery and production has been inaugurated. The plant consists of a total of 100 stills and the different units will be placed in service as fast as possible. The plant represents an investment of close to \$15,000,000.

COLUMBUS—The Board of Trustees, Ohio State University, is taking bids up to May 3 for the erection of a 1-story addition to the chemistry building, to 205 x 298 ft., and estimated to cost about \$275,000. Joseph N. Bradford, Brown Hall, State University Campus, is supervising architect.

Pennsylvania

CHARLEROI—The Electric Alloy Steel Co., manufacturer of high-speed tool steel, is completing the installation of a new electric furnace, giving the plant two 6-ton electric furnaces and one crucible furnace with an aggregate capacity of 55 tons every 24 hours. Plans are under way for the installation of another 3-ton electric furnace at a later date.

MARCUS HOOK—The Union Petroleum Co., 17 Battery Pl., New York, is reported to have plans under way for the erection of the initial units of its proposed new oil refinery on property at Marcus Hook, recently acquired. The site totals about 200 acres of land. The entire plant is estimated to cost in excess of \$5,000,000. The company is a subsidiary of the Sinclair Consolidated Oil Co., 120 B'way.

MACUNGIE, PA.—J. G. Wiedner, manufacturer of paper boxes and containers, is said to be planning for the erection of an addition to his plant, with the installation of new machinery.

Texas

SAN ANTONIO—The International Petroleum Co. has commenced work on the completion of its new local oil refinery, and plans for occupancy and operation at an early date. A. A. Ash is secretary.

HOUSTON—The Madison Coal & Oil Co., recently organized with a capital of \$3,000,000, has plans under way for the erection of a new plant in the vicinity of Navasota, Tex., for the manufacture of coal briquets. The plant will include an extensive byproducts department for the production of carbonized briquets, and the recovery of fuel oil, ammonium sulphate, pitch, tar and other chemical products. The initial plant will have a capacity of about 30 tons of briquets per hour. David M. Duller, Houston, is engineer for the company.

FORT WORTH—The Fort Worth Envelope Co., 610 West Daggett St., recently organized, has plans under way for the installation of new machinery in a local plant building for the manufacture of envelopes and other paper specialties. It is proposed to develop an output of about 250,000 envelopes per day. John A. Stafford is president, and W. C. Lowden secretary.

SOUTH BEND—The Graham Oil & Refining Co., Graham, Tex., has commenced the erection of its proposed new gasoline refinery at South Bend, and plans to have the plant ready for service at an early date. It will have an initial capacity of 1,000 bbl.

DALLAS—The Trinity Paper Mill has preliminary plans under way for the erection of a new paper pulp mill in the vicinity of McKinney, Tex. The company recently acquired the plant of the Collins County Mill & Elevator Co., near McKinney.

Virginia

RICHMOND—The Jerry Bros. Belting Co., 1823 East Main St., manufacturer of leather belting, has plans completed for the erection of an addition to its plant to cost about \$25,000. Considerable machinery will be installed, including trimming and finishing machines, presses, etc. George Gassman is manager.

West Virginia

MORGANTOWN—The United States Sheet & Window Glass Co. is reported to be planning for extensions in its local plant, to include the installation of new machinery. The company recently filed articles of incorporation with a capital of \$4,000,000. Walter A. Jones is head.

Capital Increases, Etc.

THE ROCKWOOD SILICA Co., Rockwood, Mich., has filed notice of increase in capital from \$250,000 to \$375,000.

THE SARGENT PAINT Co., Indianapolis, Ind., has filed notice of change of name to the Sargent-Gerke Co.

THE EMPIRE PAINT Co., Indianapolis, Ind., has filed notice of change of name to the Sargent-Gerke Co.

THE EMPIRE ORNAMENTAL GLASS Co., 437 Washington St., New York, N. Y., has filed notice of increase in capital from \$15,000 to \$50,000.

THE BELLEVILLE COMMERCIAL FOUNDRY Co., Belleville, Ill., has filed notice of increase in capital from \$25,000 to \$60,000.

THE D. & C. OIL Co., Bridgeport, Conn., has filed notice of increase in capital to \$50,000.

THE NEW ERA PROCESS CORK Co., New York, N. Y., has filed notice of increase in capital from \$500,000 to \$750,000.

THE COSMUS CHEMICAL Co., Muncie, Ind., has filed notice of dissolution under state laws.

THE WOLVERINE GLASS Co., Saginaw, Mich., has filed notice of increase in capital from \$125,000 to \$150,000.

THE PACIFIC BONE & FERTILIZER Co., American National Bank Bldg., San Francisco, Cal., has filed notice of increase in capital to \$300,000.

New Companies

THE FEDERAL LIGHT & REFINING Co., Newark, N. J., has been incorporated with a capital of \$200,000 to manufacture gas mantles and kindred products. The incorporators are Clarence B. White, Ambrose J. Walsh and James H. Kriek, 122 Commerce St.

THE CONCORD SMELTING & REFINING Co., Boston, Mass., has been incorporated with a capital of \$50,000 to manufacture refined metal products. The incorporators are Samuel Friedman, Boston; Bernard M. Edinberg, Roxbury, Mass. and Nathan Kositsky, Concord, Mass.

THE ELECTRO CHEMICAL REFINERIES, INC., 29 South La Salle St., Chicago, Ill., has been incorporated with a nominal capital to manufacture chemical products. The incorporators are A. M. Johnson, Burton P. Sears and Kenneth Mullins.

THE LAFAYETTE PAPER Co., New York, N. Y., has been incorporated with a capital of \$20,000 to manufacture paper goods. The incorporators are R. Robins, M. Walach and A. A. Cohen. L. M. Feinberg, 44 Court St., Brooklyn, represents the company.

THE HOLMES CHEMICAL Co., Elizabeth, N. J., has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical byproducts. The incorporators are Herbert E. Manvel, Judson H. Sencindiver, New York; and Irving J. Denton, South Orange, N. J.

THE CHARLES L. RICHARDSON Co., Boston, Mass., has been incorporated with a capital of \$10,000 to manufacture chemical products, drugs, etc. The incorporators are Charles A. Vail, M. T. Allen and C. M. Hollander, 37 Leverett St.

THE LANCASTER MIDWAY OIL Co., Whittier, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are P. H. Porter, Ray Steele and W. E. Dilts, all of Whittier.

THE PAUL RUBBER Co., Salisbury, N. C., has been incorporated with a capital of \$250,000 to manufacture rubber products. The incorporators are M. L. Miller, W. J. Daniel and E. C. Brainard, Salisbury.

THE ANDREW RAGONE Co., New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture paper products. The incorporators are G. J. Russell, D. R. Cavalla and W. A. Wight, 41 Park Row.

THE ELLICOTT PAINT Co., Buffalo, N. Y., has been incorporated with a capital of \$50,000 to manufacture paints, oils, etc. The incorporators are C. H. Nagel, G. G. Allen and E. G. Guenther. Kellogg, Babcock & Sullivan, Buffalo, represent the company.

THE MURPHY-MILES OIL Co., Room 1843, 122 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture oil products. The incorporators are Robert P. Longman, Everett Miles and Clement J. Murphy.

THE STORER RUBBER Co., Boston, Mass., has been incorporated with a capital of \$200,000 to manufacture rubber products. Fred E. Storer, 26 Fellsway, West, Somerville, Mass., is president and treasurer; Walter R. Storer and F. E. Barnes are directors.

THE STANDARD PAPER BOX Co., Detroit, Mich., has been organized to manufacture paper boxes and containers. George E. Watson and Edward C. Parker, 888 Delaware St., heads the company.

THE SCHERMULY POLARIZATOR CORP., New York, N. Y., has been incorporated with an active capital of \$20,000 to manufacture coal oil products. The incorporators are J. H. Klein, A. B. Brenner and S. Bachrach. Vanvorst, Marshall & Smith, 25 Broad St., represent the company.

C. S. LITTELL & Co., INC., New York, N. Y., has been incorporated with a capital of \$200,000 to manufacture chemicals and chemical byproducts. The incorporators are C. S. Littell, T. W. Day and C. C. Bruen, Greene & Hurd, 43 Exchange Pl., represent the company.

THE PYRO-REM CHEMICAL Co., 801 West Ninth St., Los Angeles, Cal., has filed notice of organization to manufacture chemical products. John J. Nesom, 125 West Elk St., Glendale, Cal., heads the company.

THE NITRO CHEMICAL Co., Nitro, W. Va., has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are W. D. Payne, Berkeley Minor, Jr., and C. P. Miller, Charleston, W. Va.

THE W. J. READY BRICK Co., Richmond, Va., has been incorporated with a capital of \$50,000 to manufacture bricks and other burned clay products. The incorporators are W. J. Ready and W. J. Crump, Richmond.

GEORGE F. BASSETT & Co., East Orange, N. J., has been incorporated with a capital of \$150,000 to manufacture china products. The incorporators are E. Holbrook, William B. and W. Irving Harris, East Orange.

THE SMITH-BEYER PAPER Co., Los Angeles, Cal., has been incorporated with a capital of \$100,000 to manufacture and deal in paper products. The incorporators are W. B. Smith, William Chanin and J. E. Mahon, all of Los Angeles.

RADIATED BEARINGS, INC., 127. North Dearborn St., Chicago, Ill., has been incorporated with a capital of \$100,000 to manufacture steel bearings, etc. The incorporators are A. A. and A. M. McClanahan, and Walter J. Dukes.

THE MACK PAINT PRODUCTS Co., Pittsburgh, Pa., has been incorporated with a capital of \$10,000 to manufacture paints, oils, etc. The incorporators are E. G. and R. L. McNamara, and L. Van Buren, Pittsburgh.

THE HOPEKO SUPPLY CORP., Rochester, N. Y., has been incorporated with a capital of \$100,000 to manufacture refined oil products. The incorporators are A. A. Hopeman, M. W. Hogle and F. S. Gould, Rochester.

THE MINIT PRODUCTS Co., Buffalo, N. Y., has been incorporated with a capital of \$150,000 to manufacture soap and kindred products. The incorporators are C. Whitney, J. Kaufman and A. Fybush.

THE MID-WEST DRUG & CHEMICAL Co., 1539 West Polk St., Chicago, Ill., has been organized to manufacture chemicals, drugs, etc. The company is headed by Louis Schiavone and Peter J. Spingola.

THE VITAMINE Co. OF AMERICA, INC., Jersey City, N. J., has been incorporated with a capital of 1,000 shares of stock, no par value, to manufacture chemicals and chemical byproducts. The incorporators are Harry C. Hand, Robert M. Gavett and James S. Lindsay, 15 Exchange Pl.

THE WINSTON-SALEM PAINT Co., Greenville, S. C., has been incorporated with a capital of \$10,000 to manufacture and deal in paints, oils, etc. J. L. Carson is president, and J. B. Jenkins secretary and treasurer.

THE RADIUM LABORATORIES, INC., New York, N. Y., has been incorporated with a capital of \$350,000 to manufacture chemicals and chemical byproducts. The incorporators are C. J. Dolan, J. H. Kaesen and A. C. B. McNevin, 31 Nassau St.

THE FERTILIZER CHEMICAL CORP., Fredericksburg, Va., has been incorporated with a capital of \$1,250,000 to manufacture chemicals and affiliated products. The incorporators are Paul H. Brattain and E. W. Black, both of Washington, D. C.

THE ANTHONY OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum prod-

ucts. The incorporators are C. G. Anthony, H. D. Laughlin and D. M. Sutherland, all of Los Angeles. The company is represented by B. J. Bradner, 911 Wright & Callender Bldg.,

THE NEW MILFORD CHEMICAL Co., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture chemicals and chemical byproducts. The incorporators are P. Cifini, J. Mazza and F. Balzerini. The company is represented by Ryan, Hefferman & Dawn, 25 West 45th St.

THE STANDARD POURED BRICK Co., Miami, Fla., has been incorporated with a capital of \$100,000 to manufacture cement brick and kindred specialties. The incorporators are L. R. Nordquist and J. L. Holmberg, Miami.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its seventh annual convention at the Hotel Lafayette, Buffalo, N. Y., on May 9, 10 and 11.

AMERICAN CHEMICAL SOCIETY is holding its sixty-first meeting at Rochester, N. Y., April 26 to 29. Headquarters are at the Hotel Rochester.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN WELDING SOCIETY will hold its annual meeting April 27 to 30 in the Engineering Societies Building, New York City.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

CHAMBER OF COMMERCE OF THE UNITED STATES will hold its ninth annual meeting in Atlantic City April 27, 28 and 29.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-eighth annual convention at the Greenbrier Hotel, White Sulphur Springs, W. Va., the week beginning June 20.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF INDUSTRIAL ENGINEERS will hold a meeting in Milwaukee April 27 to 29.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month; except June, July, August and September.

TANNERS' COUNCIL OF THE UNITED STATES will hold its annual spring convention at the Hotel Traymore, Atlantic City, May 5 and 6.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Sunday Clothes

For Chemists' Ideas

THE following is a true story of the proceeds to various parties engaged in the development of a chemical enterprise:

To the chemist for the "idea" together with process and plans	\$ 5,000
To the lawyer for legal services in organization....	50,000
To the broker for services in floating the new company	100,000
To the owner, net returns in three years.....	300,000

The chemist, the lawyer and the broker, all three, contributed information. It probably took the chemist longer to see the process through than it did the lawyer to draw up the papers, or the broker to get the subscriptions. But time spent is no gage of the value of professional services. The question is one of intrinsic value. Relatively speaking, the chemist was the parent of the establishment, and the lawyer was its nurse; and outside a divorce court we seldom hear of a nurse who gets all but one and two-thirds per cent of a parent's possessions. There is something wrong in the apportionment of that \$55,000. Either the lawyer got too much or the chemist did not get enough. Both contributed professional services. We shall not attempt to bring into consideration as this time the broker's wage. His work is social rather than professional. He knows men, knows how to get their confidence and to induce them to give up their savings. If the owner knew men better he would not need the broker and if the chemist knew men and their ways better he would get a better fee for his own work.

We need more business in chemistry. If a chemist enters the employment of another man or of a corporation, then whatever he discovers in connection with his employment belongs to his employer. We maintain this, no matter how differently some others may feel. But when he becomes consultant the traditions are against him. He is supposed to work by the hour, like a hod-carrier, at cost plus a bare living. Chemistry has the tradition of being cheap and easy to hire.

There is a strategic reason for this. The chemist comes along first. He is the man with the idea. One can take it or leave it, and it is very easy to pass it by. So few persons want the idea that he soon bids against himself to get it taken up. The lawyer comes in when the money has been spent and trouble looms in the offing. He doesn't worry. Whatever happens he gets his reward. And he has learned how to charge for his services. The chemist has not.

Of course there are a great many poor chemists; men of whom negative results may be predicted almost with certainty. But there are also a great many poor lawyers. As such they are trouble-makers, and the wise man does not retain them. He knows lawyers. But he does not know chemists save once in a thousand

times; and he is not wholly to blame for it either. He doesn't know how to go about it to find out the best men available.

What chemists need is Sunday clothes for their ideas; silks and satins and scarlet and velvet for the public to admire and desire. Now the art of presenting ideas so that they are desired and regarded as valuable is called business, whether it has to do with selling goods or negotiating loans or securing subscriptions to an underwriting. Chemists need more business in chemistry to make it pay and to give the profession its proper standing among men.

Nutrition and the

Road to Pleasant Living

THE Chandler lecture at Columbia University was given this year on April 18 by Dr. F. GOWLAND HOPKINS, professor of biological chemistry, Cambridge, England, on the subject, "Newer Aspects of the Nutrition Problem." Prof. HOPKINS is one of the leading men in the chemistry of nutrition, and it was he who first recognized the necessity of some theretofore unknown accessories to the diet of fats, carbohydrates and proteins now known under the general term of vitamins. A large part of the great gift of the Rockefeller Foundation for research in medical science in England has been set aside for work under Dr. HOPKINS and his associates.

He made an earnest appeal for more work and more workers in this field of supreme importance. The tendency in the last few years, he said, has been for physical chemists to enter the field, and the value of their contributions has been exceedingly great. It enables us to arrive at knowledge which generations have been waiting for, and their methods of reaching results are rapid. In metabolism, however, there are problems which involve chemical reactions that are still unknown, and the distinctions between living and diseased tissues can be learned only by the study of molecular structure; therefore the need extends also for those whose work and experience and habit of thought have to do with organic chemistry.

We noted certain signals of warning to the effect that vitamins have lately come in for more attention and discussion than their functions would seem to warrant, bearing in mind the many other features of similar importance in metabolism. The lecturer also urged us not to forget the differences in metabolism between a large organism such as the body of a man and a small one such as the body of a rat or a guinea pig, in reaching conclusions from experiment.

The social effect of advance in understanding the chemistry of nutrition may be greater than most of us appreciate. Apart from what Prof. HOPKINS told us it would seem to point the way not only toward better

health but toward better living conditions. Suppose it were possible to cut down the cost of wholesome and agreeable foods to a much lower figure than that which now obtains. There are signs of it already. Many men in posts of authority whose rewards for service are so high that the cost of meals is not considered are going over to a much simpler diet than that of the day laborer. The cost of preparation at expensive restaurants is high, but that is due to the accessories such as furnishings, tableware, table linen, service, including high rents, more than to the food, or even to its preparation.

This brings us around to a favorite thesis, to the sermon we have been preaching for several years past, and that is that the road to pleasant living is not through wealth, but rather through interest and curiosity. The interest to which we refer is not the earning power of bonds, but the same word in another sense—to wit, the quality of interest in various topics which is akin to curiosity. Therefore whoever has an intellectual ambition, or whose interest in any subject within the arts and sciences is aroused, he may work by the day and yet be a remarkably free man. When the day is over, his task is done and the best of art and literature is open to him. This is not the case of the employer or those with creative intellects whose work is never done, and who cannot address themselves with the same seriousness to the graces of life. Their spare time is not really free. True, art and literature have a hard time these days among those who belong to what is technically known as the ranks of labor, but these same ranks of labor have the golden opportunity to advance themselves in scholarship, in learning and in the newer humanities. Therefore a possible concomitant of research in nutrition may be a very widespread and distinguished culture among those who work with their hands.

The Overtones of Efficiency

IN THE May number of the *North American Review* a member of our staff presents a popular essay on "Relativity and Life." The thesis is that relativity has been known as a philosophic concept for many years, but that EINSTEIN was the first to present it as a scientific principle in which dimensions are determined and eventually measured and compared. It is proposed that this may be done in fields more generally familiar than that of cosmic physics, and dimensions are sought for liberty and other ideas which are under daily discussion. It is held that the dimensions of liberty are freedom and service; that freedom is a more restricted concept than we generally admit, and that without service, rendered either by ourselves or by others, we cannot enjoy liberty. Rights are declared to emanate from liberty, to rest on liberty, and it is maintained that there is no such thing as a single or independent right. In resting on liberty, rights also rest on service, which is a dimension of liberty.

It is possible that this postulate may aid us in planning work. In the consideration of service we have not been disposed to measure it; our disposition has been to get as much of it as we can at the lowest cost. Or, if we render service, it has been our disposition to get as much as we can for it, irrespective of its measurement. What we have neglected is the *obligation* of service. We think so little of the obligation of service that it does not enter into the romance of our generation; we do not find it save on rare occasions, in fiction

or in the drama or in moving pictures. The most frequent idea seems to be that if some hero or heroine is pleasing and affable and does the day's work acceptably, then the reward is a great inheritance of wealth which in turn is a reward of service that has been rendered by somebody else.

The jingle of dollars, however, is not enough to hold the public attention. The public demands more of human interest than a bank account or a big storage vault for securities. So there is introduced what is technically called heart interest, which is usually sex interest, and everybody is satisfied when the hero and heroine, one of whom is rich and the other poor, agree to get married.

Now we do not want the drama's conventional heart interest in industry, and yet we do need some kind of a real heart interest in it. We need something in every organization that will induce every one connected with it to desire to give service for a cause.

If we compare a present-day stone mason with one of the thirteenth century we find the modern mason getting better pay, working shorter hours, but wholly indifferent to the building he is working on. He doesn't know and doesn't care what the building is to be. The foreman has blueprints to guide him in directing the work, and the easier it is the better everybody likes it. It is less "bother" if it is easy. The mediæval mason, on the other hand, knew all about the building, knew its purpose, knew he was building for time, had opportunity to exercise his own ingenuity in carving as well as laying the stone, and he was doubtless proud that he had a hand in the work.

In industry it behooves us to seek its purpose, the purpose that makes it so desired that the product is wanted. If a man cannot be proud in having a hand in his work, there is something lacking. Industrial life needs larger thinking than it has enjoyed: more thinking and less belligerence.

As a rule labor is still unwilling to take chances on production. Labor and employers can agree on a minimum wage and an interest in profits, but when the profits go down labor usually strikes at the reduction. It isn't always so, but it happens too often to make profit-sharing a workable practice, even when employees would welcome it. But beyond the wages there is something needed to encourage service. It is a perplexing question, but that is what makes it interesting. This is the overtone to the jingle of dollars, to the commodity price paid for work. It could even be mathematically expressed if we knew it better.

If we bear in mind that our liberties and our rights emanate from services, our own or those of somebody else, it will make us all less bumptious in our claims and more willing in our work. We cannot as American citizens live upon the liberty achieved by the founders of the republic. We shall use it up in no time unless we ourselves do constantly contribute; contribute more than we require for ourselves. We cannot run away from our obligations.

The trouble is that we do not learn what our obligations are by having them preached at us. We must discover them for ourselves. We are more inclined to do this when we see somebody else seeking and finding his responsibilities and fulfilling them. To sense obligations and to fulfill them is an achievement in character rather than an art or an inheritance. Right conditions induce it, and to find and provide the right conditions is the greatest problem in industry today.

Federal Trade Commission

Accepts Judge Gary's Invitation

FORMAL complaint has been issued by the Federal Trade Commission against the Steel Corporation and its subsidiaries, alleging unfair methods of competition in violation of section 5 of the commission's organic act and section 2 of the Clayton act. The complaint is made upon application of the Western Association of Rolled Steel Consumers and other users of steel products, and is the outgrowth of conditions complained of by more than 2,700 fabricators of steel in the Chicago, Duluth and Birmingham districts, by legislatures of three states, by several municipalities and by chambers of commerce and by many business organizations.

In brief, the applicants complain against the device known as the Pittsburgh plus price. Under this device all steel except rails, wherever made and whether made by the Steel Corporation plants or by independents, is sold at the Pittsburgh price plus an amount equivalent to freight to point of destination, irrespective of whether the cost of production at the plants outside of Pittsburgh is less, as it generally is, than the cost of production in Pittsburgh. The "Birmingham" price is also complained of, which is described as the Pittsburgh price plus an additional charge of \$5 a ton.

The complaint charges that the Steel Corporation has complete control, supervision and direction over the subsidiaries, transportation materials used in the manufacture of iron and steel and products made therefrom in interstate commerce; that the corporation through certain of its subsidiaries owns and controls over 75 per cent of the total iron ore deposits in the Lake Superior district, where is located the greater part of the iron ore deposits of the United States; that it owns and controls the greater part of the iron ore deposits of Alabama, where production is second only to that of the Lake Superior district; that it owns and controls the ultimate iron ore supply of the United States; that it owns and controls the major number of railroads and lake transportation systems which carry iron ore from mines to manufacturing plants of its subsidiaries and their competitors, and that it likewise owns and controls coal mines and limestone quarries necessary in the manufacture of steel.

The complaint charges that of the total production in the United States of the following items respondents manufacture and sell approximately 47 per cent of the crude steel in the form of ingots; 45 per cent of semi-finished rolled steel in the form of billets, blooms and slabs and sheet and tin plate bars; 45 per cent of finished rolled iron and steel products in the form of rails, plates and sheets, structural fabrics, bars, iron rods, skelp, hoops, bands, cotton ties, etc., and 60 per cent of other steel products.

Paragraph 5 of the complaint charges that the corporation for at least seven years has issued from time to time price quotations and schedules covering rolled steel manufactured by its subsidiaries and that these quotations are adopted by all the subsidiaries and their competitors substantially as their prices.

Paragraph 5 also recites that because of the power and influence of the corporation through the large percentage of the steel-manufacturing business done by it and supported by it the consequent potential power to embarrass or destroy its competitors by unduly lowering its price schedules is tantamount to the naming by the Steel Corporation of prices that are to be charged by all steel manufacturers in the United States.

This proceeding by the Federal Trade Commission was urged by Judge GARY, chairman of the board of the Steel Corporation, at a preliminary hearing in Washington on July 9, 1919. When questioned by the commission at that time as to whether he thought it had jurisdiction, he replied affirmatively and that it was a question that ought to be taken up and settled by the commission. He added: "It is one of the most important questions you ever had before you, or ever will have before you." He also said that the principle of the Pittsburgh plus price plan was duplicated in whole or in part in a great majority of the other basic industries of the country.

Of course, the substance of the complaint is: Pittsburgh, the high-cost-producer, gets the bulk of the business at a profit arbitrarily decreed; plants elsewhere get additional profits because of their lower costs of production; every increase in transportation rates means additional profits to the plants outside of Pittsburgh, because the amount of the increased rate is added to the selling price.

The investigation has been invited by the head of the Steel Corporation. The invitation has been accepted by the Federal Trade Commission. It is well that it should proceed. If, as Judge GARY says, the practice is followed in the other basic industries of the country, such should be brought out. If it is a good thing, its wisdom should be established. If it is not, but makes merely an added burden which the consumer has to pay, its abolition should be decreed, not only in the steel industry but in all others where it prevails.

Artistic Influence

In Scientific Development

The Past as clear as Polished Glass appears
While Dark as Lacquer seem the Coming Years;
Yet, mirrored in the Past, the Eye may see
The Faces of the Centuries-to-Be.

FAR back in the dim ages as the time may have been when the potter first employed his hands to coil character and clay into expressions of beauty he developed a spirit of accomplishment which has been handed down to our present day ceramists. With this tradition of idealism in their hearts a few of today's old-timers assembled some twenty years ago and founded the American Ceramic Society.

Now a large national organization, its principal activities are centered on the application of chemistry and physics to technical problems, and human understanding to problems of organization and trade development in the clay-working industries. That this same influence carries the work along and that the ceramists are anxious to preserve it to future generations was crystallized in the formation of a new art division of the society at the annual convention in February.

Other events at this meeting plainly indicated the field of the future in the bringing of the heavy clay industries together for research into methods of scientific control, in the pleas that manufacturers forego degeneration consequent upon secrecy of process, and in the plans for broadening of business activities to an international scope.

The trend of the growth of American ceramics clearly appears in many details and it may be definitely predicted that the ideals of the artist will be a continued constructive influence in the scientific development of the calling.

Readers' Views and Comments

Activities of Fixed Nitrogen Research Laboratory

To the Editor of Chemical & Metallurgical Engineering

SIR:—I have read with much interest the article by Dr. R. C. Tolman on "Government Fixed Nitrogen Research" in your journal of April 6, 1921, page 595, and feel myself obliged to comment upon some of the propositions inferentially laid down by Dr. Tolman.

In order to clear the ground I may say that I believe as firmly as Dr. Tolman does that research in the problem of fixing nitrogen is the most important thing at present before the world. It is an old saying, and probably a true one, that what enabled us to pay off the debt of the civil war and cure inflation by "resumption of specie payments" was the invention of the twine binder, which, together with the unoccupied lands of the West, enabled us rather suddenly to make an immense addition to our productive power. All the world is at present staggering under war debts; and the man who makes "two blades of grass grow where one grew before" is more than ever a public benefactor. He is wanted by all the world. To clear off these debts quickly, not only in this country but all over the world, we need again an immense increase in production; and one way to get it is to grow more food to support more workers in industry. This can be done by cheaper fertilizer enabling the farmer to make a decent profit from cheap food.

Without going into the question of how far this necessary research work should be done by the Government and how far it should be done by private enterprise, I may say that any information that expert skill in the service of the Government can contribute toward this matter is welcome—welcome to all of us. It should, however, be noted that in this country experience teaches us not to be very sanguine as to Government activity in business.

Where I differ from Dr. Tolman, in the first place, is in his assumption all through his article that the results which his laboratory obtains may properly be kept secret from the public. As he states it, if the Government is to run certain plants, then and in that event all results of his work are to be kept "confidential"; which means that they are not to be disclosed to the public at large. Now I personally have a very vivid interest in the problem of fixing nitrogen, and I am a taxpayer. I feel that the results of Government work in this line, if any, should be made public and not held in secret archives of the Government. I must therefore register a protest against any such policy of bureaucratic secretiveness.

Secondly, I must question the choice of lines of investigation. Mainly this research work is to be done upon the cyanamide and the Haber processes. Now as it happens both these matters are more or less covered by patents. Is it the proposition that the Government is to do work in this line which is to be kept secret from the public and which either will inure largely to private benefit—namely, to those gentlemen who happen to have a financial interest in the Haber process and in the cyanamide process—or else will form the basis of Government competition with such interests?

I also dissent on general principles from the idea that this work shall be mainly limited to these two lines. The cyanamide process, Dr. Tolman states, is at present "the only means by which nitrogen can be fixed in America in case of emergency"; but he also virtually admits that after a while it must be dropped. With the latter admission I am in accord. For generations the price of inorganic nitrogen for fertilizer purposes has fluctuated around 15c. per lb., that being the datum plane set by Chilean saltpeter. About 3c. a lb. being the Chilean export duty, we are now, on a consumption of 200,000 tons of nitrogen, annually paying tribute of about \$12,000,000, partly to Chile, but mostly to help make it interesting to capital to invest in byproduct coke ovens (illustrating, by the way, the workings of protection). Very little of this tribute goes to the cyanamide interests. Even with such stimulation, the only cyanamide plant operating in America after about fifteen years of development is in Canada. If we may set 5c. nitrogen as a goal of fixation activity, it is pretty certain that we must find a faster vehicle than the cyanamide process.

Taking the second main proposition, the Haber process has already been worked out very well in Germany and I do not know that there is any great secret as to the results which the Germans get. They appear to be still some distance from the 5c. mark. Various private interests in this country now know as much on paper as the Germans do. I therefore very much question the advisability of spending Government money for duplicating this information, and particularly if the information is to be kept "confidential." If not kept confidential and used in competition with private enterprise it will inure to the benefit of my friend the General Chemical Co., which knows most of it anyhow.

Dr. Tolman is perfectly sound in his reluctance to go very far into the arc process; but feeling as he does, I am surprised that he is putting even \$14,000 into equipment for it. I would suggest that \$14,000 spent in Norway would probably bring more information than \$14,000 spent here. It is a truism in research work that it is better to start things where the other fellow left off; and in Norway they have spent many dollars and much time in learning about the process.

Finally, I must take exception to the casual way in which fixation in the form of cyanide is dismissed. While it is perfectly true that the Bucher process got into trouble because of the inherent difficulty in transmitting large amounts of heat through a retort wall to an open and pervious charge undergoing endothermic action, yet the fact remains that cyanide formation is, so to speak, the only way of fixation to which nitrogen seems to take naturally and easily. In other ways nitrogen must be bludgeoned into combination by electricity or pressed with the very purest of hydrogen, but into cyanide the nitrogen goes because it seems to feel like it. The energy involved is about 8,000 units, suggesting a material and fuel cost under ½c. a lb.

Acyanide process makes rather intriguing promises. I might recommend that Dr. Tolman, if he is going to continue these investigations, pay more attention to

cyanide and less to other things; but again there is the inherent difficulty that if he does so the results either will injure or will benefit private interests. Yet, even so, on the principle of equal opportunity and non-discrimination, I am constrained to suggest that a fair share of any appropriation for nitrogen fixation be devoted to the development of the cyanide method.

Ferro Chemicals, Inc.,
Washington, D. C.

R. FRANCHOT.

SIR:—The Fixed Nitrogen Research Laboratory always welcomes constructive suggestions, such as Mr. Franchot's, as to the policy which it should adopt.

With regard to Mr. Franchot's first suggestion, I may say that the War Department has kept the results of the work of the laboratory confidential in order that they might be available solely to the U. S. Fixed Nitrogen Corporation, which was contemplated in the Wadsworth bill, which failed to pass during the last session. Assuming that the failure of this bill means that the Government is not itself going to undertake the fixation of nitrogen, it is obvious that there is no longer any necessity for keeping the researches of the laboratory secret. In fact, the laboratory has no justification for existence unless the information which it obtains is put to some useful purpose, either by the Government or by private industry, and the laboratory is now definitely recommending to the War Department that the results of its researches be published.

With regard to the relative amount of attention which the laboratory has paid to the different methods of nitrogen fixation, the greatest emphasis has in the past been put on the cyanamide and the Haber processes, in order that information should be available for the governmental operation of the Muscle Shoals plant, which at the time the laboratory was founded seemed probable, and in order that the Haber plant at Sheffield might be reconstructed.

In the future more emphasis will be put on other methods of nitrogen fixation, and as a matter of fact for some time the laboratory has been planning work on the cyanide process.

RICHARD C. TOLMAN.

Commercializing Priestley's Theory

To the Editor of Chemical & Metallurgical Engineering

SIR:—Your recent article and correspondence anent the subject of "Easy Money From Peat"* recalled to me a similar experience which I had a few years ago, which may be of interest in this connection.

I was called upon to investigate the composition of a liquid being widely promoted as a carbon remover for gasoline engines. The action of this liquid was claimed to be due to its property of liberating *gaseous oxygen* when submitted to a *pressure* of 50 lb. or more. When mixed with the gasoline in the proportion of about 1 oz. to 5 gal. sufficient liquid was supposed to be carried into the cylinder with the vaporized gasoline to compensate for the large volume of nitrogen in the air of a combustion mixture by means of this oxygen!

Upon casual investigation this truly remarkable substance seemed to be composed chiefly of kerosene with small quantities of naphthalene alcohol and amyl acetate common to similar preparations.

The quantity of oxygen claimed to be liberated was, if I remember correctly, not less than 10 liters per

cubic centimeter! Aside from the improbability of any substance decomposing in this way under the influence of pressure, which would naturally tend to have the reverse effect, I attempted to point out that such a volume of oxygen would weigh considerably more than the total weight of the liquid from which it was obtained, but found that this apparent difficulty had been disposed of by the ingenious inventor. I was gravely informed that "according to the Priestley theory" pure oxygen possessed no weight whatsoever, the mass ordinarily found associated with this substance being due entirely to impurities therein.

Upon the failure of the technical experts of this project to put in an appearance at several conferences and demonstrations which we attempted to arrange the subject was dropped, but it seems unfortunate to allow modern chemical science to struggle along without the marvelous benefits which would doubtless accrue from the judicious application of the "Priestley theory."

New York City.

GUSTAVE REINBERG, JR.

Important British Fertilizer Supplies

Up to ten years ago the names of the Island of Nauru and Ocean Island were practically unknown to any save the geographer and the specialist. They are tiny specks of land lying in one of the loneliest spaces of the Pacific Ocean fifty miles south of the Equator and 3,000 miles west of the South American coast.

In 1885 these islands, which were considered of no commercial value, were formally annexed by Germany. Some time afterward phosphate deposits were discovered on Ocean Island and some years later on Nauru. One of the effects of the world upheaval of August, 1914, was the formal transfer of these German islands to Great Britain under the terms of a mandate. An agreement was made on July 2, 1919, between the governments of the United Kingdom, the Commonwealth of Australia and the Dominion of New Zealand for the allotment of British-controlled phosphates in the Pacific Ocean on the basis of 42 per cent to the United Kingdom, 42 per cent to Australia and 16 per cent to New Zealand.

It now appears that the British Empire has acquired one of the richest supplies of phosphates in the world, reports Commercial Attaché Dennis, of London. It is stated that the formation of these phosphate deposits has been accomplished largely through the agency of fish-fed sea birds which have left vast deposits of guano on the islands. These deposits, mingling with the lime of the coral rocks, have practically converted the whole of the islands into great repositories of phosphate of lime. These phosphate deposits run to a depth of 40 ft. on Nauru and 57 ft. on Ocean Island. A representative sample of this island phosphate yields:

	Per Cent
Moisture sample:	
Water	3.87
Tribasic phosphate of lime.....	82.56
Ground sample (dried):	
Carbonic acid	2.06
Equal to carbonate of lime	4.69
Phosphoric acid	39.34
Equal to tribasic phosphate of lime.....	85.89
Oxide of iron and alumina.....	0.76
Organic matter and combined water	2.86

Neither island possesses harbor facilities. It has been necessary, therefore, to construct jetties, of the cantilever type, running far out over the reefs. From these the phosphate is lightered to steamers. The present annual production of the islands is in the neighborhood of 250,000 tons.

Italian Chemical Industries

FROM OUR SPECIAL CORRESPONDENT

GENOA, ITALY, April 15, 1921.

THROUGH the large quantities of German war reparation chemicals and dyestuffs delivered to Italy this country was not only overstocked with some products but the national producers suffered severely through the great reduction in the prices that followed. Therefore a movement was begun to stop or at least reduce the supply of some of these products from Germany, and replace them with others of which Italy is still in great need.

FOREIGN EXCHANGE SINKS STRONGLY

After several months of very high foreign exchange, that had demonstrated only a very slight tendency toward reduction, a sudden fall took place toward the middle of March, bringing down with it all prices. Business, already very dull, came in many cases to a complete standstill, old stocks being used up by many, while others suspended manufacturing operations awaiting events. Italian metals, minerals and chemicals received a further fall, and so did Sicilian products such as sulphur, essences, sumac leaves, manna, mannite, tartaric acid, citric acid, cream of tartar, etc., creating a panic among holders of such products, many of whom tried to sell their stocks, often not finding buyers.

NEW DECREE ON BENZENE FOR CHEMICAL WORKS

To assist and encourage manufacturing operations where benzene is employed largely, the Italian Government has arranged a specially reduced importation tariff of two lire per 100 kilos on benzene and other light coal-tar oils destined to serve as raw materials for the production of artificial organic coloring matters or varnishes and similar products. Such benzene must, however, be submitted to a certain degree of adulteration at the expense of the buyers. The adulterant will be established for the different industries by the Minister of Finances.

NEW WATER-POWER AND HYDRO-ELECTRIC DEVELOPMENTS IN ITALY

Different projects are being studied for utilizing the water power available in the Trentino. One proposal is to form an independent corporation controlling the property of different Italian and Tyrolese industrials and of several municipalities, and another is to utilize the Noce Torrent, collecting a portion of its waters in a large reservoir in the Palu Valley and a portion in a second reservoir constructed between Pelizzano and Mezzana. The extensions of fields and woods would thus be occupied by two large artificial lakes, and the valley of Palu would be dammed by a stone dike 75 m. high and 65 m. thick, inclosing a volume of water of a possible volume of 38,000,000 cu.m. (about 50,000,000 cu.yd.), covering a surface of about 900,000 sq.m. (about 1,100,000 sq.yd.). The water power derived from these lakes would permit the production of 150,000 to 180,000 electric horse power.

Development of the Italian hydro-electric companies has increased considerably. Although these once possessed a total capital of only 600,000,000 lire, today their capital is 1,500,000,000 lire, an increase of 180 per cent. The Italian Government gave no support in this instance; on the contrary it receives 70,000,000 lire per year in taxes and other fixed rights. During

the five years 1915-1920, 265,000 electric horse power obtained from new hydraulic plants was put in operation, and at present plants are under construction for harnessing more than 400,000 horse power. The capital needed to bring to completion similar plants is calculated at 1,200,000,000 lire. Other plants are also in contemplation to bring into being another million horse power.

TECHNICAL DIRECTORS MEET

At a meeting in Milan recently of the new association of technical directors, to which members came from Piedmont, Liguria, Lombardy, Veneto and Emilia, the industrial and financial situation of Italy was closely examined, and it was generally conceded that the labor-control experiments conducted in some works only tended toward general disorganization and to a loss of authority and initiative on the part of technical directors and industrials. It was decided to call the attention of all absent technical directors to this state of affairs in the hope of getting their co-operation in solving the problem.

A CONVENTIONAL EXCHANGE

The use of a conventional, or reduced, foreign exchange with England and France seems to have taken a certain development during March. A similar arrangement appears, however, to have been made by many Italian and foreign firms for the last six months and during the war whenever the exchange made a great increase that would have stopped or reduced business. Many foreign exporters could thus conduct their business as in normal times and without great danger of loss. By this arrangement the buyer deposits to the credit of the foreign sellers in an Italian bank the value of the goods purchased at a reduced exchange arranged by both sides. This deposit then remains in Italy until it is most profitable for the seller to draw it out. The foreign seller does not, however, lose the use of the whole sum, for he can obtain from any bank in his country a loan of 75 per cent on it, and at the worst loses only the difference of interest on the foreign loan and Italian credit.

ITALIAN FERTILIZERS

The serious difficulties encountered in the supplies of fertilizers, and especially of perphosphates, decreased considerably during March, owing to greater activity on the part of Italian fertilizer works, which began the construction of new works and extended older works. Italian production of sulphate of copper and of nitrogenized fertilizers such as cyanamide, nitrate of ammonia, etc., was also increased and much improved.

ITALIAN LITHOPONE INDUSTRY

The manufacture of lithopone is conducted in only one works, at Brescia, belonging to the Milan firm Attilio Gelpi, which produces only a few hundred kilos per day, although the zinc and barium minerals necessary are particularly abundant. For this reason the greater part of the product used here has to be imported. During March a campaign was begun to increase the production of this important substitute for carbonate of lead, and it is hoped means will be found for large future developments. This would seem to be an excellent opportunity for the investment of American capital. Germany is already trying to do something in this direction, but her initiative is not looked upon with favor. Before the war the zinc and barium minerals were largely exported. This is, however, no longer profitable, owing to the high transportation expenses.

The Crystalline Structure of Metals

A Brief Definition of Crystallinity; a Discussion of the Methods Used in X-Ray Analysis of Atomic Spacing; and a Statement of the Results of Such Studies Made to the Present Time

By ZAY JEFFRIES AND R. S. ARCHER
Research Bureau, Aluminum Company of America

IT IS PERHAPS because we are accustomed to associate regularity of external form, brittleness and transparency with the crystalline state that it seems somewhat strange to regard ordinary pieces of metal as crystalline. The essence of crystallinity, however, lies in regularity of internal structure, and it has been abundantly proved that all metals are crystalline. Study of their crystalline structure has led to very clear conceptions of the mechanism of deformation and failure, and recently to a general theory of the strength of alloys.¹ The application of X-ray analysis has made our knowledge of crystal structure more complete and exact, and is clearly destined to play an important part in the future development of metallographic science.

Crystallinity depends upon an orderly arrangement of the molecules of a substance. In the molten condition or in solution in a solvent the molecules are arranged in an entirely haphazard manner. On the other hand, when the substance crystallizes, the molecules group themselves according to definite and repeating patterns. Metals are monatomic—that is, their molecules contain only one atom. The case under consideration in this paper is thus simplified in that the atom is the unit in the pattern.

SPACE LATTICES

The pattern which forms the foundation upon which a crystal is built is known as a *space lattice*. It consists of a series of points in space such that every point is situated similarly to every other point. Space may be imagined as divided into cells by three sets of parallel planes. The planes of each set are at equal distances from each other and parallel; the distance between planes may be different in the various systems, and the three sets of planes may make any angles with each other. The points of intersection of these planes constitute a space lattice, as is illustrated in Fig. 1.

The arrangement of atoms in planes is responsible for the characteristic and commonly observed properties of crystals. For instance, when a crystal is allowed free development, it assumes a form bounded by plane faces. The direction, or orientation, of these faces is determined by the lattice underlying the crystal. Similarly, it is found that crystalline bodies often possess the property of breaking easily along certain planes, called cleavage planes. Deformation of metals takes place by sliding on planes known as slip planes, as will be described later. In any given crystal the orientation of the cleavage planes and slip planes is fixed. When a crystalline substance is subjected to attack by a chemical solvent, it is found that the resistance to solution is

greatest on certain planes. The planes determining external form, cleavage, slip and resistance to chemical attack are planes which pass through atom centers in the space lattice. It will readily be seen that a very large number of sets of parallel planes could be drawn which would pass through all of the atoms, but the significant planes are limited to those on which the concentration of atoms is large.

SYMMETRY

Any plane passing through a crystal in such a way that the atoms on one side occupy the positions of mirror images of those on the opposite side is a *plane of symmetry*.

Two kinds of planes of symmetry are distinguished. If the structure on one side of the plane can be rotated on the plane through some angle (other than 180 deg.) without destroying the symmetry, the plane is said to be a *principal plane of symmetry*. If such rotation destroys the symmetry for all positions other than the

FIG. 1. THREE SETS OF PARALLEL PLANES WHOSE INTERSECTIONS FORM A PARTICULAR SPACE LATTICE (BRAGG)

original or one reached after a rotation of 180 deg. then the plane is called a *secondary plane of symmetry*. To express this more mathematically, principal planes contain two or more equivalent and interchangeable directions, while secondary planes possess no interchangeable directions.

An axis of symmetry is a line through a crystal such that a revolution about it through some angle less than 360 deg. will result in a duplication of the original position of the crystal. The degree of symmetry with respect to the axis depends on the number of times during a complete revolution that such duplication occurs. When such a condition is brought about by a revolution of 180 deg., or twice during a complete revolution, the crystal is said to possess a twofold or binary symmetry. Similarly the classification is extended to threefold or

¹This theory, which the authors have called the "slip interference" theory, will form the subject of another article to appear soon.

ternary, fourfold or quadratic, and sixfold or hexagonal symmetry. Axes of more than twofold symmetry are called principal axes of symmetry. Twofold or binary axes are called secondary axes.

In considering their structural characteristics, crystalline bodies are looked upon as extending indefinitely, in all directions. The planes and axes referred to represent directions rather than specific planes or lines. Other planes through atom centers parallel to a plane of symmetry are likewise planes of symmetry of exactly the same kind. When we say that the isometric system possesses three principal planes of symmetry, we mean that there are three sets of parallel planes any one of which is a principal plane of symmetry for a crystal extending indefinitely in all directions.

ISOMETRIC OR CUBIC SYSTEM

The direction of a crystallographic plane is defined by referring it to a system of axes chosen with respect to the particular crystal system under consideration. The cubic or isometric system, which is the simplest and also the most common among metals, will serve to illustrate the method of designation. Axes OX , OY and OZ (Fig. 2) are in this case the intersections of the three principal planes of symmetry. They are perpendicular

FIG. 2. SKETCH OF CUBIC CRYSTAL ILLUSTRATING SYMMETRY (BRAGG)

to each other and are said to be of equal length, meaning that the same scale is used to represent distances on all the axes, and there is nothing inherent which distinguishes one from the other.

Plane ABC is called the ground plane. In all systems one of the parameters² of the ground plane is taken as unity for simplicity of reference, and the other parameters are then fixed in accordance with the nature of the system. In the isometric system all of the parameters of the ground plane are equal, and hence unity and plane ABC intersects all axes at equal distances from the origin.

The *indices* of a plane are the reciprocals of the parameters, and planes are more usually designated by indices. The planes noted in Fig. 2 have indices as follows:

ABC	(111)	$CDEF$	(011)
$CDGE$	(001)	$DGBF$	(010)

The directions of OA , OB and OC in Fig. 2 are considered positive, and the opposite directions negative.

If the parameter of a plane is negative, then the corresponding index is negative and it is written with the negative sign above the index. If the parameters of a certain plane are $OA = -2$, $OB = 1$, $OC = 1$, the indices are $\bar{2}, 1, 1$. Since, however, indices and parameters express only ratios, not the actual position of a particular plane but the direction of a series of parallel planes, the indices $(\bar{2}, 1, 1)$ are the same, crystallographically, as $(\bar{1}, 2, 2)$, $(\bar{2}, 4, 4)$, etc. Writing without commas, $\bar{1}22$ is used because it has no fractions and has at least one index unity. The above system of notation is the Miller system.

CRYSTAL SYSTEMS

All possible crystal structures can be divided into six groups, each characterized by a particular grade of symmetry³:

1. *Isometric or Cubic System*.—Three principal and six secondary planes of symmetry. Crystals referable to three equal rectangular axes. Most metals belong to this system.

2. *Tetragonal System*.—One principal and four secondary planes of symmetry. Crystals referable to three rectangular axes, only two of which are equal. No metals are definitely known to belong to this system, with the possible exception of tin.

3. *Hexagonal System*.—One principal and six secondary planes of symmetry. Crystals referable to four axes, three of which lie in the same plane intersecting at 120 deg., and are equal in length. The fourth axis is perpendicular to the plane of the three others at their intersection and may have either greater or less length. The metals magnesium, zinc and cadmium belong to this system.

There are three other systems—namely, orthorhombic, monoclinic and triclinic, in which no metals are known to crystallize.

VISIBLE METALLIC CRYSTALS

Under some circumstances the crystalline nature of metals becomes apparent to the unaided eye. The crystalline appearance of the zinc on iron galvanized by the hot dip process is familiar to everyone. Similar regularity of external form is frequently produced when metals solidify with one surface free from restraint. Fig. 3 shows the surface of a piece of cast tellurium which solidified in an open mold.

During solidification of a metal crystallization begins at centers called nuclei, and proceeds in a directional manner. Growth is most rapid along some line which bears a simple relation to the symmetry of the crystal. A trunk shoots out in this direction and branches grow out from the sides of the trunk parallel to one another and in directions determined by the structure of the crystal. The result is a formation which from its resemblance to a tree is called a *dendrite*. The dendritic appearance of many of the crystals can easily be seen in the photograph of tellurium, Fig. 3. Because of the fact that most metals contract on solidifying, the dendrites which form on the surface of a metal are left in relief by the contraction of the mother liquor.

Since several nuclei form simultaneously and growth proceeds in all directions (especially when the nuclei are completely surrounded by the molten metal), it is obvious that adjacent crystals growing toward one an-

²The parameters of any plane are the intercepts on the axes of reference. The parameters of plane $CDGE$, for example, are $\infty, \infty, 1$ and $(OC) = 1$.

³"Elementary Crystallography," by W. S. Bayley; McGraw-Hill Book Co.

FIG. 3. FIR-TREE CRYSTALS ON SURFACE OF CAST TELLURIUM. $\times 2$

other must meet. If a single crystal is allowed to develop from a molten bath, its external shape will be a fairly perfect geometrical figure. With a large number of growing crystals, however, as the molten metal becomes exhausted the crystals must meet in such a manner as to fill the space completely. These crystals will be oriented in different ways, and hence in order to fill space cannot form their habitual external shapes. Such a crystal with orderly arrangement of the atoms in the interior but an external shape determined by the influence of other crystals is called an *allotriomorphic crystal*, or *crystallite*, or more commonly a *grain*. In any given grain, therefore, the atoms are arranged in the same manner as they would be in a perfect crystal of the metal, but the grain may have any external shape.

No two adjacent grains in a cast metal have the same orientation. By orientation is meant the direction of the crystallographic axes. If two adjacent grains had the same orientation, the boundary between them would disappear and the two grains would become one. A metal, therefore, which has solidified from the molten state consists of an aggregate of differently oriented grains. These grains vary widely in size and shape, according to the specific crystallizing properties of the metal itself, the rate of cooling through the solidifica-

tion range, the temperature gradients, purity and other factors. Sometimes the grains are so large that they can readily be seen with the unaided eye and at other times they are so small that a microscope is required to see them.

ETCHING POLISHED SECTIONS

For examination under the microscope a piece of metal must be ground or filed flat and then carefully polished. Examination then reveals no structure whatever, except for particles of included foreign matter such as slag and oxides. The boundaries of the grains themselves are not distinguishable. It has been suggested by Beilby⁴ that the process of polishing has produced a surface layer of amorphous metal which is opaque and covers the crystalline metal underneath. This amorphous layer can be dissolved in a chemical reagent in which the metal is soluble. The process of chemical attack on the polished surface is called *etching*. The boundaries between the grains are regions of low resistance to chemical attack and their location is shown after light etching.

Deeper etching develops marked differences in color between different grains, some appearing dark and others light. The process of solution produces minute facets, which vary in orientation from one grain to another. Light falling on an etched surface will be reflected into the microscope only by such facets as have the appropriate orientation. These grains will appear light, while other grains will appear darker. The different tints of the grains are therefore evidence of their crystallinity and of their different orientations.

Still deeper etching often produces within certain grains geometrical figures which are called etching pits. These pits approximate a definite geometrical form, such as a triangle or rectangle, and within any particular grain have the same form and orientation. They furnish additional evidence of the crystallinity of metals.

The various effects of etching just described are shown in Figs. 4, 5 and 6, taken from a specimen of nearly pure iron (Armco iron).

INTRACRYSTALLINE SLIP

If a piece of ductile metal is polished and etched to bring out the grain boundaries, and is then subjected to a load which causes a slight permanent deformation, examination under the microscope reveals systems of parallel lines running across the grains. In any one

⁴"The Hard and Soft States in Metals," by Sir George Beilby; May lecture, Institute of Metals, 1911.

FIGS. 4, 5 AND 6. ARMCO IRON, AFTER VARIOUS ETCHINGS

Fig. 4. Light etching, developing grain boundaries. $\times 40$

Fig. 5. Moderate etching; various grains having different tones. $\times 40$.

Fig. 6. Deep etching, developing so-called etching pits. $\times 800$.

grain the lines are approximately straight and parallel to one another, but their direction is different in different grains. In the first stages of deformation only a few of these lines appear, and not in every grain. As the deformation increases more lines appear, becoming closer together and appearing in grains previously free from them. Finally other sets of lines are developed, parallel to one another in any one grain and crossing the first set of lines. Close examination shows that the first sets of lines have been displaced along the second sets by a minute amount, so that they no longer register exactly.

The nature of these lines has been very carefully investigated,⁵ and they are known to represent block movement or slip along crystallographic planes. The lines observed are steps on the polished surface produced by the elevation or depression of blocks or fragments of the grains. They are called *slip bands* and the crystallographic planes along which slip occurs are called *slip planes*. A slip band becomes visible under the microscope only when the displacement along the slip plane is on the order of 0.00001 in., which corresponds roughly to 1,000 atom diameters. Displacements have been measured as high as 0.00005 in., or about 5,000 atom diameters. Even greater movements probably occur in severe deformation.

COLD-WORK OR PLASTIC DEFORMATION

The great permanent deformations imposed on metals in the various processes of mechanical working, such as rolling, forging and drawing, are substantially integrations of very many block movements along slip planes. This type of deformation is called plastic deformation, as opposed to fluid deformation, which is characteristic of liquids and of amorphous solids like pitch and glass. In plastic deformation relative motion is confined to the slip planes, the crystalline fragments between such planes moving as units in which the atoms retain substantially their initial relative positions with respect to their neighbors.

When the external shape of a piece of metal is changed by a deforming load, the shapes of the grains undergo similar changes. Normally, the grains are so shaped that on the average their diameters are equal in all directions. Such grains are called equiaxed grains. Now if the metal is deformed as by drawing out into a wire, the grains are similarly drawn out. The change in the external shape of a grain is made up of a multitude of minute slips each so small that the grain retains an apparently smooth outline. In Fig. 7 is shown a section through the piece of iron shown in Figs. 4 and 5, after compressing it cold until its height was reduced about 60 per cent. A much greater degree of deformation is represented in Fig. 8, a section through a piece of drawn tungsten wire. The specimen shown in Fig. 7 was repolished and etched after being compressed, a procedure which effaces slip bands. However, lines are visible within the grains which are undoubtedly due to the cold deformation. Rosenhain considers these to be the traces of slip planes on the plane of the micro-section. Howe is less certain of their nature, and calls them "X-bands."

Grain deformations are permanent when effected be-

low a temperature known as the annealing temperature or recrystallization temperature. If the metal is subsequently heated above that temperature, the grains recrystallize into new grains which have a tendency toward equiaxial shape and bear little relation to the old grains. If the deformation is carried out above the annealing temperature, the mechanism is substantially the same, except that the metal anneals during the working. Mechanical work carried out on a metal above the annealing temperature is called hot-working, while if the temperature is below the annealing temperature it is called cold-working. Cold-work results in a distorted structure and increased hardness. Hot-working produces a normal structure without any hardening. Cold-working followed by annealing has similar effects to hot-working.

When a ductile or malleable crystal (or grain) is loaded sufficiently to cause failure along some crystallographic plane, the fragments formed cohere, and deformation takes place without rupture. The atoms of one fragment are not sufficiently removed from those of the others to lose cohesion permanently. When a brittle crystal is broken, fracture takes place usually along the crystallographic cleavage planes, and the fragments formed do not stick together. A crystal that is brittle

FIGS. 7 AND 8

Fig. 7. Armco iron, cold-rolled; 60 per cent reduction. Compare Fig. 4. $\times 40$.

Fig. 8. Extreme deformation of crystalline grain in tungsten wire reduced 98.8 per cent by swaging. $\times 160$.

at one temperature may be ductile at a higher temperature. Crystals that are brittle under ordinary conditions of loading may be capable of undergoing plastic deformation under increased hydrostatic pressure. Bismuth and antimony, for example, which are ordinarily quite brittle, can be extruded into wires when sufficient pressure is applied in such a way that the metal is confined on all sides. Increase of pressure brings the atoms into closer contact, facilitating the re-establishment of cohesion bonds along the planes of failure. Increase of temperature serves the same purpose by increasing the amplitude of atomic vibrations.

Brittle metals, such as chromium and manganese, break without permanent deformation, and their cleavage planes are clearly revealed. The fracture then looks crystalline. Ductile metals break only after the grains are greatly drawn out and slip has taken place on very many planes. The fracture then has a more or less fibrous appearance which does not suggest the inherent crystalline nature of the metal. The same piece of metal, however, when subjected to repeated applications of stress, breaks along the crystallographic planes with practically no permanent deformation, and the fracture may appear crystalline. It is often said that the fatigue has caused the metal to "crystallize," whereas in reality the peculiar manner of failure has merely revealed the crystalline structure already present.

⁵"The Metallography of Steel and Cast Iron," by Henry Marion Howe; McGraw-Hill Book Co. Ewing and Rosenhain, "The Crystalline Structure of Metals," *Phil. Trans.*, vol. 195, p. 279. TWINNED CRYSTALS

Sometimes grains grow together in such a manner that they are symmetrical structurally with respect to a plane between them. These are called twin crystals. Usually the twinning is of such a nature that if either part of the twin were revolved a certain amount about an axis perpendicular to the twinning plane the two parts would possess the same orientation and would merge. Sometimes several parallel twinning planes occur so that each alternate crystalline strip has the same orientation. This is called polysynthetic twinning. Fig. 9 shows this type of twinning in alpha brass, a solid solution possessing the essential structural characteristics of pure metal. Fig. 10 shows slip bands in alpha brass twins. It will be noted that these slip bands are continuous through each grain, but change direction at each twinning plane.

These twins in brass were produced on annealing after cold-working. Twins produced in this way are generally called *annealing twins*, to distinguish them from mechanical twins, which are formed in some metals, notably alpha iron and zinc, by cold deformation alone. Mechanical twins, in fact, are removed by annealing. Mechanical twins appearing in iron as narrow dark bands are known as Neumann bands or Neumann lines. They are parallel to certain crystallographic planes.

X-RAY ANALYSIS OF OPAQUE CRYSTALS

Our study of the structure of metals is limited by the wave length of the light we use. With the highest powered microscopes available it is possible to distinguish separate particles whose diameters are not less than about one one-hundred thousandth of an inch. It is theoretically possible approximately to double this resolving power by using ultra-violet light of short wave length, but this has not so far been accomplished in a practical manner. At the best, visibility or photography is limited to distances on the order of 1,000 atom diameters.

Within the past decade methods of crystal analysis by means of X-rays have been developed by Laue, Bragg and Bragg,⁶ Hull⁷ and others, which extend the field of investigation down to the atom itself. X-rays are entirely similar to visible light but have wave lengths of the same order of magnitude as the distances between atoms in crystals. It has been possible by their use to determine not only the arrangements of the atoms in metals but the exact distances between them.

The fundamental principle of these methods is similar to that of the ordinary diffraction grating, which consists of a piece of glass or metal on which are ruled a great many parallel and equidistant lines. A beam of monochromatic light falling upon such a grating is diffracted through an angle depending on the wave length of the light and the spacing of the lines on the grating. When white light falls upon the grating, the rays of different wave lengths (or color) are diffracted through different angles, thus forming a spectrum. The grating can be used for the analysis of light and for the exact measurement of the wave length of any particular portion of the spectrum. Or, conversely, monochromatic light of known wave length may be used to determine the spacing of the lines on an unknown grating.

The wave lengths of X-rays are about one ten-thousandth as large as those of visible light, and it would be entirely impossible to construct a grating of appropriate spacings by the usual method of ruling lines. It occurred to Laue that the ordered arrangements of the atoms or molecules in crystals might be used for the investigation of X-rays, since the spacings of the planes of atoms (or molecules) are of the right order of magnitude. This idea has been successfully developed experimentally. The first problem was to verify the supposition that X-rays were indeed of undulatory character like ordinary light, and to measure their wave lengths. The process could then be reversed, using monochromatic X-rays of known wave length to measure the spacing of the planes of atoms in a crystal.

The problem differs from that of the ordinary grating in that the crystal grating extends over three

FIG. 11. REFLECTION OF X-RAYS BY ATOMS (BRAGG)

dimensions. The principle⁸ can be explained by reference to Fig. 11. The lines p, p, p , etc., represent planes of atoms in a crystal, separated by a common distance d . A, A', A'', A''' , etc., are a train of advancing waves of X-rays of wave length λ . Consider that these rays are partly reflected from each plane according to the usual law that the angle of incidence is equal to the angle of reflection. Only a small part is reflected at each plane, the remainder penetrating deeper into the crystal.

Consider any path of reflection as BC , which is parallel to all other paths of reflection and typical of them. The waves $AB, A'B', A''B''$, etc., join in reflection along BC . These waves are in phase with one another at $AA'A''A'''$, a line perpendicular to the direction of propagation. If they remain in phase with one another after reflection along BC , reinforcement will take place and a strong beam will result. If they are not in phase, the rays will be lost by interference. The necessary condition for reinforcement is that the

⁶"X-Rays and Crystal Structure," by W. H. Bragg and W. L. Bragg; G. Bell and Sons.

⁷"A New Method of X-Ray Crystal Analysis," *Phys. Rev.*, vol. 10, No. 6, December, 1917.

⁸"Roentgen Rays and Crystal Structure," *METALLURGICAL & CHEMICAL ENGINEERING*, vol. 15, p. 35 (July 1, 1916).

difference in the paths of these waves must be an integral multiple of the wave length.⁶ Let us express this condition mathematically:

Draw BN perpendicular to AB . Draw BD perpendicular to pp . Prolong $A'B'$ to D . Then:

$$A'B'C' - ABC = (A'D + BC) - (A'N + BC) \\ = A'D - A'N = DN$$

$$DN = 2d \sin \theta$$

Therefore

$$n\lambda = 2d \sin \theta \quad (1)$$

where n is any whole number.

This is the fundamental equation. It expresses the fact that in order for strong reflection to occur, the glancing angle θ must have one of certain definite values. These values are given by:

$$\lambda = 2d \sin \theta_1 \\ 2\lambda = 2d \sin \theta_2 \\ 3\lambda = 2d \sin \theta_3, \text{ etc.}$$

The reflection at the angle θ_1 is called the reflection of the first order, that at the angle θ_2 reflection of the second order, and so on. The possible number of reflections is limited for given values of d and λ , since $\sin \theta$ cannot have a value greater than 1.

Then in the limit:

$$n\lambda = 2d \\ n = \frac{2d}{\lambda} \quad (2)$$

For example, if the spacing, atom to atom, equals 5×10^{-8} cm., and the wave length in use is 3.5×10^{-8}

cm., $n = \frac{2 \times 5 \times 10^{-8}}{3.5 \times 10^{-8}} = 2.85$. Reflections of the first and second order only are possible.

Now let us represent an experimental set-up by the line drawing of Fig. 12.

FIG. 12. DIAGRAM OF APPARATUS FOR CRYSTAL ANALYSIS

$A-A$ is a pencil of monochromatic X-rays. B is a crystal having crystallographic planes (planes of atoms) as indicated by the fine parallel lines. B is mounted on a pedestal capable of rotation about an axis perpendicular to the plane of the paper.

C is a device for detecting X-rays, such as an ionization chamber. (X-rays have the property of ionizing gases, thereby causing them to conduct electricity. The conductivity of the gas in the chamber C can be measured by means of an electroscope, which gives a measure of the intensity of X-radiation entering C .) C is mounted to swing on the arc indicated about the same axis as B . By rotating B on its axis and C along its arc, several conjugate positions can be found for which strong reflections will enter C , corresponding to the various orders of reflection. The angles θ_1 , θ_2 , etc., can readily be measured and, given

the wave length of the radiation, the spacing of the planes of atoms can be calculated in accordance with the equation (1).

By choosing different faces of the crystal, this process can be repeated so as to give the spacings of the various sets of parallel planes, from which data the arrangement of the points in the space lattice can be deduced.

HULL'S METHOD OF CRYSTAL ANALYSIS

Suppose that the crystal B in Fig. 12 is properly oriented for a reflection of the first order. If a photographic film DE is interposed perpendicular to the beam AB , the diffracted beam will strike it at the point D , on the path of BC . The principal beam AB will for the most part not be diffracted, and will strike the film at E . Now suppose the crystal to be so mounted that it can be rotated about $A-A$ as an axis; during the rotation, the correct glancing angle θ_1 will be preserved, and the diffracted beam BDC will draw on the film a circle about E as a center. One complete rotation of the crystal will cause it to assume successively all of the positions from which it is capable of sending out a reflection of the first order from the particular set of planes in question. The diffracted beam generates a cone of light about $A-A$ as an axis. A film interposed cuts out a circle, which is thus the locus of all the possible first-order reflections from this set of planes.

For reflections of higher orders, other circles will be drawn on the film, having diameters increasing with the order of the reflection. It will of course be necessary to reset the crystal to the proper glancing angle in each case before carrying out the rotation about $A-A$.

Now suppose the crystal to have its orientation so altered that another set of crystallographic planes diffracts beams on to the film. If we repeat the above process of setting the crystal to the proper glancing angles and rotating it about $A-A$, we will obtain another set of circles representing the various orders of reflection. If the spacing of the planes differs from that of the first set, the circles will have different diameters, corresponding to the different glancing angles involved.

This process might be repeated for every set of crystallographic planes. The result would be a series of concentric circles. Each circle would be proof of the presence of a set of planes having that particular spacing capable of diffracting a beam through the angle represented by the circle.

Instead of carrying out this process by the systematic method of setting the crystal and rotating it about $A-A$, we might simply cause the crystal to assume successively all possible orientations. We would then get exactly the same pattern of concentric circles. Or, if instead of a single crystal, we choose as our specimen a very large number of small crystals, of thoroughly mixed orientation, we obtain again the same result, without rotating the specimen.

This is the foundation of Hull's generalized method of crystal analysis, or the method of powders.⁷ A fine grained metal possesses the same properties as a powder for this purpose, since it is an aggregate of crystalline grains of mixed orientation. Smaller specimens can be used if they are rotated, as this gives the effect of a greater number of crystal orientations. A single photograph of such a specimen gives all of the possible circles and hence the spacings of all pos-

sible crystallographic planes. A diffraction pattern of aluminum obtained by this method is shown in Fig. 13. In actual practice it is customary to photograph only one quadrant of the pattern, and to bend the film into the arc of a circle so that the distances between the lines cut from the large circles are proportional to the angles involved. Patterns of this type are shown in Figs. 14 and 15. Fig. 14, in fact, may be considered a magnified section of a portion of Fig. 13. It was photographed on a film bent around an arc about B , whereas Fig. 13 was a flat plate; consequently the ratios of the distances between successive lines do not have a simple arithmetical relation. However, two bright lines are followed by a broad space, a bright line, a narrow space, two close lines, one brighter than the other, etc.

ATOMIC ARRANGEMENT

In this discussion we have necessarily been obliged to omit consideration of many important details, in order to simplify the presentation of the essential principles. It is also beyond the scope of this article to go into the actual synthesis of crystal structures from the data obtained by these methods, subjects which are completely discussed in the appended references. For the present we shall confine ourselves to the presentation and discussion of some of the results thus far obtained on metals. The arrangement of atoms in metals has been found to be extremely simple.

The most simple arrangement possible is one in which

the atoms occupy positions at the corners of a system of equal closely packed cubes. This is known as the simple cubic arrangement. No metals or other elementary substances have been found to have this arrangement, but it is typical of salts composed of equal numbers of positive and negative ions, such as the alkali halides. The most common arrangement in metals is the face-centered cubic arrangement, shown in Fig. 16, where the atoms are at the corners of a system of equal closely packed cubes and also at the centers of each cube face. This arrangement may be considered as formed by two simple cubic lattices intersecting each other in such a manner that the corner atoms of one lattice fall at the centers of the faces of the other lattice. All of the atoms in the face-centered arrangement are in reality similarly situated. Any particular set of atoms may be equally well regarded as corner atoms or as face atoms. Each atom is surrounded by twelve equidistant and symmetrically situated atoms. This arrangement is one of two which furnish the closest possible packing for a number of equal balls. It is accordingly sometimes referred to as the cubic close-packed arrangement.

The next most common arrangement is built upon a unit cube having an atom at each corner and one at the center. This is illustrated in Fig. 17. The corner atoms and center atoms are interchangeable, so that if the system of lines in Fig. 17 had started with one of the center atoms all the corner atoms would become center atoms, and *vice versa*. Each atom is surrounded

FIG. 13. DIFFRACTION PATTERN OF ALUMINUM (HULL)

by eight equally distant and symmetrically situated atoms. This arrangement is not so closely packed as the face-centered arrangement.

There is one other arrangement found in metals, known as the hexagonal close-packed arrangement (Fig. 18). It is equally close packed with the face-centered cubic. The space occupied by a crystal of this sort may be regarded as built up of a series of equal closely packed right triangular prisms whose bases are equilateral triangles. The altitudes of the prisms are equal to 1.633 times the length of the sides of the triangles. An atom is located at each prism corner and at alternate

The study of the positions of atoms in metals is so recent that only a few generalities can be drawn at present. Some features which may be mentioned are:

1. No metal crystallizing with the face-centered cubic arrangement has been found so far which is not ductile throughout a considerable range of temperature. The face-centered metals are usually ductile even at liquid air temperatures.

2. All of the noble metals so far studied crystallize with the face-centered cubic arrangement.

3. All of the best electrical and heat conductors have face-centered cubic arrangements.

FIG. 14. DIFFRACTION PATTERN OF ALUMINUM, PHOTOGRAPHED ON CURVED FILM (HULL)
FIG. 15. DIFFRACTION PATTERN OF MOLYBDENUM (HULL)

prism centers. Each atom is therefore surrounded by twelve other equidistant atoms, as in the face-centered cubic arrangement, but not quite so symmetrically.

The following table by Hull⁹ gives information on the positions of atoms in several metals. (1 Angstrom is 0.00000001 cm. = 10^{-8} cm.):

Metal	Arrangement of Atoms	Length of Side of Elementary Cube in Angstroms	Distance Between Centers of Nearest Atoms in Angstroms
Aluminum.....	Face-centered cubic.....	4.05	2.86
Cobalt ¹⁰	Face-centered cubic.....	3.57	2.52
Nickel.....	Face-centered cubic.....	3.54	2.50
Copper.....	Face-centered cubic.....	3.60	2.54
Rhodium.....	Face-centered cubic.....	3.82	2.70
Silver.....	Face-centered cubic.....	4.06	2.87
Platinum.....	Face-centered cubic.....	4.02	2.85
Gold.....	Face-centered cubic.....	4.08	2.88
Lead.....	Face-centered cubic.....	4.92	3.48
Lithium.....	Centered cubic.....	3.50	3.03
Sodium.....	Centered cubic.....	4.30	3.72
Chromium.....	Centered cubic.....	2.91	2.52
Iron.....	Centered cubic.....	2.86	2.48
Molybdenum.....	Centered cubic.....	3.15	2.73
Tungsten.....	Centered cubic.....	3.15	2.73
Magnesium.....	Hexagonal (close packed).....		3.22
Zinc.....	Hexagonal (close packed).....		2.84
Cadmium.....	Hexagonal (close packed).....		3.15
Cobalt ¹⁰	Hexagonal (close packed).....		2.53

⁹"The Position of Atoms in Metals," American Institute of Electrical Engineers, 1919.

¹⁰The case of cobalt is exceptional in that both the hexagonal and cubic close-packed arrangements are found.

4. Both ductile and brittle metals are found in the body-centered cubic arrangement. This system seems to be less favorable to ductility than the face-centered, according to Hull.

5. In the hexagonal arrangement both brittle and ductile metals are found. In ductile hexagonal metals the temperature range in which ductility obtains is relatively small. Hull points out that in the hexagonal arrangement there is only one set of planes parallel to which easy gliding can take place, whereas in the face-centered cubic there are four.

6. Metals having the hexagonal close-packed arrangement harden rapidly under cold deformation.

7. Mechanical twinning (Neumann lines) occurs in metals having the centered cubic and the hexagonal close-packed arrangements. Alpha iron is an example of the former and zinc of the latter. Mechanical twins have also been observed in tin, which is thought to crystallize in the tetragonal system.

8. Annealing twins are certainly most prevalent in metals crystallizing in the face-centered cubic arrangement.

9. Annealing twins have not been observed in metals

FIG. 16

Fig. 16. Face centered cubic arrangement of atoms; or cubic close packing (Hull).

FIG. 17

FIG. 18

Fig. 18. Hexagonal close-packed arrangement (Hull).

FIGS. 16, 17 AND 18

having the centered-cubic arrangement, such as alpha iron, tungsten and molybdenum.

10. Not all face-centered metals show twinning. Twin crystals have not been observed in aluminum, for example.

ALLOTROPY

Several of the metals are known to exist in two or more allotropic modifications. The most important case is that of iron. Steel owes its remarkable capacity for hardening to the fact that at high temperatures iron exists in the form of gamma iron having a very considerable solvent power for carbon, while alpha iron, the form stable at ordinary temperatures, has in comparison no such solvent power.

It has been difficult to define allotropy in a certain manner. The new information on crystal structure suggests that an allotropic change may be defined as a change in atomic arrangement. This definition should furnish a positive criterion of allotropy, hindered only by the experimental difficulties involved in determining atomic arrangements at high temperatures.

The gamma form of pure iron is stable only above 900 deg. C., and its atomic arrangement has never been determined. It is possible, however, by means of certain alloying elements to preserve at room temperatures solid solutions, denoted by the generic term austenite, which are isomorphous with gamma iron. Such an austenitic steel is obtained, for example, by the use of about 13 per cent manganese. This material has been examined by Jeffries and Bain and found to possess the face-centered cubic arrangement, which may therefore be assumed to be the arrangement in gamma iron. In common with other metals having this arrangement of atoms, austenitic steels are very ductile, and also show twinning. The fact that the face-centered cubic arrangement is more closely packed than the centered cubic arrangement accords nicely with the expansion noted when gamma iron transforms into non-gamma.

The arrangement of atoms in several solid solution alloys has been investigated by Hull, Davies and Andrews of the General Electric Co. It seems that the atoms of the solute generally replace those of the solvent without substantial change in the arrangement or spacing. If two metals have different crystalline arrangements there may be a certain range of composition within which both arrangements are found simultaneously.

Although intermetallic compounds have not been studied with the X-ray, it seems obvious that in the crystal lattice the atoms of the different elements are not interchangeable, as they appear to be in solid solutions.

The information to be yielded by the X-ray analysis of metals has only begun to accumulate. We may confidently expect further important results in the future, concerning in particular the constitution of metallic solid solutions and of intermetallic compounds. The methods should also enable us to detect the presence of a second physical phase in a metal, such as a highly dispersed intermetallic compound, when the particles of this phase are too fine for resolution by the microscope. Altogether, the advent of the X-ray spectrometer at the present time promises to be about as important an event in the history of metallurgy as was the introduction of the microscope in the latter part of the last century.

Supply of Potash in Illinois Shale

The discovery of shale in Illinois which may prove a cheap American source of potassium for agricultural purposes, and which is rich enough in potassium to increase the yield of certain crops grown on peaty soil as much as 180 per cent, is announced by the University of Illinois. Tests have been in progress since 1915 to find a source of potassium.

The experiments carried on under greenhouse control indicate marked benefit to crops resulting from applications of the shale. The shale produced an increase in the yield of sweet clover of 168 per cent; of rape, 96 per cent; of corn fodder, 146 per cent, and of buckwheat, 180 per cent. These results were obtained on peaty soil in pot-culture work.

There is also some indication, according to the university, that the shale may serve as a source of potassium for gray silt loam, another type of Illinois soil. In the production of buckwheat, there was an increase from use of shale of 32 per cent in the grain and 19 per cent in the straw. Corn fodder also showed increases.

Shales which contain 5 per cent or more of potash occur in at least two localities in Illinois. Outcropping in several places near Jonesboro, in Union County, which contains 5 per cent of potash would be suitable, so far as can be determined from its chemical composition and physical character, for use in the manufacture of portland cement. By using this material in the manufacture of cement and by applying the known methods of potash recovery, a yield of 5.3 lb. of potash, representing a value of 70c. to 80c. per barrel of cement, could be obtained. Shale from Dixon, Lee County, contains 5.8 per cent of potash, which is held for the most part in a more stable condition than that in the southern Illinois shale.

While further experimentation will be necessary to determine whether these potassium compounds can be made available under field conditions, enough has been done to show not only the presence of vast amounts of this valuable material in Illinois shales, but also to demonstrate that the compounds are capable of reduction by agricultural plants grown under laboratory conditions.

Agricultural Experiment Station Bulletin 232 just off the press at the University of Illinois, Urbana, Ill., describes in detail the research carried on by S. W. Parr and M. M. Austin in the chemical laboratory. Part II of the same bulletin covers the geology of the subject investigated by Frank Krey. Part III covers the work of Robert Stewart, chief in soil fertility at the university, who determined the action of these shales in soil improvement for growing plants.

Chemical Tonnage on Class 1 Railroads

In analyzing the freight tonnage handled by the Class 1 railroads during the last quarter of 1920, the Interstate Commerce Commission finds that chemicals and explosives furnished 1,987,141 tons of freight. Fertilizers are shown separately and account for 981,935 tons more.

By far the greater part of the chemical and explosives tonnage of the country is handled by the railroads in the Eastern district, where the amount is shown to have been 1,286,457 tons. The Western district was in second place with 352,186 tons, while the railroads of the Southern district handled 257,309 tons.

A Device for Measuring the Flow of Gases

BY CARLE R. HAYWARD*

DURING some tests in the metallurgical laboratory of the Massachusetts Institute of Technology it became necessary to measure the flow of gas from a cylinder of liquid SO_2 . The nature of the gas prevented the use of an ordinary meter and the amount was so small that the change in weight of the cylinder was not

FIG. 1. PRESSURE DIFFERENTIAL GAS METER

easily measured. It was also desirable to change the rate of flow at will.

The apparatus devised for the above purpose is shown in the sketch (Fig. 1). The fundamental principle is well known, but some features of construction are believed to be new. The device is easily made and is so useful that a brief description may be of interest.

The body consists of a piece of ordinary 3-in. steel pipe, 8 in. long capped at both ends. A hole is bored in each cap and threaded to receive short lengths of $\frac{1}{4}$ -in. pipe as shown. The pipe from one cap is fitted with a T into which is put a short piece of $\frac{1}{8}$ -in. pipe. The side of the 3-in. pipe is also bored to receive a piece of $\frac{1}{8}$ -in. pipe. Each of the $\frac{1}{8}$ -in. pipes is connected to one arm of a U manometer which may contain either mercury or water according to pressure used. The gas flows in the direction indicated by the arrows.

The pipe leading out of the pressure chamber is threaded to receive a brass plug *P*, through which a small hole is bored. A series of these plugs is kept on

*Assistant Professor of Metallurgy, Massachusetts Institute of Technology.

FIG. 2. CURVE WHEN CAPILLARY TUBE IS USED

hand with holes varying in size from $\frac{1}{16}$ in. to $\frac{1}{8}$ in. The plugs can be easily changed by removing the cap from the large pipe. For very small flows a piece of broken thermometer tube has been cemented in the pipe in place of the plug.

The operation of the meter is self-evident from a study of the sketch. The flow of gas through the orifice in the plug *P* depends on the size of the orifice and the difference in pressure on the two sides of the plug. The latter is measured by the manometer. Precautions must be taken to have all joints tight.

The flow through each plug was determined for different manometer readings by connecting the meter to a compressed air line and measuring the flow with a gas meter, or in the case of very small volumes by displacing water in a graduated tube. Having determined the flow for each inch difference in pressure, the results are plotted in a curve. The general shape of these calibration curves is shown in Figs. 2 and 3.

After determining the curve for each plug the meter is available for use on any gas. The writer has used it for SO_2 , hydrogen and air in volumes varying from 3 liters per hour to 100 liters per minute. Pressures have varied from 1 in. of water to 30 in. of mercury.

It is possible to use the meter with the gas flowing

FIG. 3. CURVE WHEN NO CAPILLARY TUBE IS USED

in the direction opposite to that shown in the sketch, but the adjustment when used in that way does not seem so sensitive under the high gas pressures thus far used. It is possible that with low initial gas pressures it would be more satisfactory.

The original suggestion for using pipe fittings for this device was made by Henry M. Schleicher, to whom credit is gladly given.

Municipal Sulphuric Acid Plant Proposed

It is reported that there is under consideration the building of a sulphuric acid plant by Bradford in connection with the city's sewage works, reports Consul Young, of Bradford, England. This plant uses large quantities of sulphuric acid for precipitation purposes.

Before the war the sewage department paid 25s. (\$6.08) a ton for the acid. At the present time the cost is about £6 (\$29.20). At this latter figure it is estimated that £100,000 (\$486,650) for sulphuric acid will be needed annually, and it is believed that if the sewage committee built its own works the acid could be produced at less than half the present cost.

Present Status of Fruit and Vegetable Dehydration

Results of Investigation and Fundamental Principles of Operation and Construction of Fruit and Vegetable Dehydrating Plants—Advantages of Dehydration—Data on Air Volume, Thermal Units and Humidities Required

BY WILLIAM V. CRUESS

Assistant Professor of Fruit Products, University of California

AS A result of the stimulus of government orders for dehydrated vegetables for army use during the World War many firms in different parts of the United States and Canada undertook the large-scale production of Julienne (vegetable soup mixture), dehydrated potatoes, onions, carrots, spinach and other vegetables. A few of these manufacturers had previous experience in dehydration, but to most of them the industry was new. With assistance from officers of the quartermasters corps, investigators of the U. S. Department of Agriculture and state experiment stations most of these new plants were soon placed upon a satisfactory producing basis. Considering the many difficulties to be met in vegetable dehydration, the rapid rate of progress made by those who undertook to supply the army with dehydrated products is truly remarkable.

The success obtained in producing dehydrated vegetables for the army led a number of firms immediately after the close of the war to attempt the dehydration and sale of dehydrated fruits and vegetables for civilian use. To create a demand they relied upon the high quality of their product, its cheapness and convenience. Some of the pamphlets issued by newly organized dehydration companies painted a most rosy future for the dehydration industry and promised large and quick returns to those who should invest in the new enterprise.

Evidently these overoptimistic promoters were "ahead of the times," because most of them have fallen by the wayside and nothing remains of their ill-fated projects except unpaid bills and idle evaporators.

There are, however, several very well-financed corporations managed by men who not only know the many advantages of dehydrated foods but who also realize the need of popularizing such foods and of educating the housewife, through advertising, to change her age-old custom of using fresh vegetables only when she can get

them and doing without when fresh vegetables are not in season.

There has also been another condition to blame for the present slump in dehydration. A considerable amount of inferior dehydrated vegetables has been produced and has created an unfavorable impression upon those who have purchased it. Through carelessness or lack of technical knowledge on the part of some manufacturers, dehydrated products have developed lusty infestations of the Indian meal moth (*Plodia interpunctella*) after leaving the factory. Both of these conditions have now to a very great degree been removed; the first by virtue of the fact that most of the inexperienced operators of dehydrators are bankrupt and the second because the manufacturers now know how to prevent insect infestation.

COMMERCIAL OPERATIONS

At the present time one corporation in Oregon, the Kings Food Products Co., is operating two large plants representing an investment of over half a million dollars. Dehydrated fruits are the principal products. These find a ready market at prices considerably above those paid for the average "run" of evaporated fruits and the profits from these fruits in a large measure "pay the way" for the development and advertising of the dehydrated vegetables produced by this same company. Over \$500,000 has been spent by this one firm in national and local advertising. Its owners state that they would welcome competition from other concerns which would produce dehydrated vegetables and fruits of the highest quality in order that the popularization of dehydrated foods might be hastened. This firm has recently been capitalized for \$10,000,000 and will establish new plants in addition to expanding the two now in operation.

In California a large plant has been built and is operated by the Caladero Products Co., a subsidiary of the Atascadero Colony. It represents an investment of over \$200,000 and has been one of the most successful of the large dehydrators on the Pacific Coast. The products are advertised through the columns of the colony's monthly illustrated *Review*, a journal with a wide circulation. The company is now specializing upon pumpkin flour, which is ground dehydrated pumpkin put up in canisters for the preparation of pumpkin pies. The product is excellent in flavor and color and very convenient to use. It has met with great favor and gives promise of becoming a staple article of trade.

The Japanese farmers of southern California have erected in Los Angeles a modern dehydrating plant equipped with modern machinery. They have made a special effort to popularize a dehydrated soup mixture. The plant is used as a means of converting surplus

FIG. 1. INTERNATIONAL DEHYDRATORS

vegetables in times of overproduction into marketable products. The company is known as the California Evaporated Products Co. and markets its dehydrated products under the name "Cepco."

In Chicago the Anhydrous Food Products Co. has recently launched upon a campaign of expansion, and its development is watched with great interest by those interested in dehydration on the Pacific Coast. Dehydration of sweet corn is, in the writer's estimation, by far the best of the dehydrated vegetables so far produced. Sweet corn is reported to have been dehydrated by the carload in several Eastern states during the past season.

Other companies might be mentioned, but the situation is perhaps best summarized by stating that the dehydration industry is now on a well-established basis in several states, but will require a great deal of money for advertising purposes before it becomes a major food preservation industry. Development also depends upon standardization of equipment and processes. Time and sustained effort on the part of American dehydration companies will be needed to place this industry upon the basis that the advantages of the dehydration process warrant.

In European countries the advantages of dehydration have been recognized more universally than in America. Germany possessed, it is stated by Prescott and Sweet, in 1906, 36 dehydration plants; in 1909, 199; in 1914, 488 and in 1917, about 1,900 plants. Some of these were "built-over" breweries. The amount of potatoes dried in Germany in 1917 was more than three times the total crop of the United States for that year. These facts afford one reason why Germany was able to maintain her food supply during the war.

The writer has recently seen dehydrated vegetables in compressed brick form which had been exported to the United States from Holland in commercial quantities. These were of very excellent quality.

ADVANTAGES OF DEHYDRATION

It is stated that 20 to 40 per cent of all fresh fruits and vegetables spoil between the producer and the consumer. Dehydration offers an economical and thoroughly satisfactory means of converting such surplus into non-perishable products. As the population of the world increases and the struggle for existence becomes more keen, dehydration may well serve to increase the available food supply by reducing waste through spoiling of fresh products. It can serve to stabilize production and markets by making it possible to store one year's overproduction for use in a year of underproduction.

One of the most evident advantages of dehydrated foods is their small bulk and weight. Many vegetables lose 80 to 95 per cent of their weight in drying and decrease to from one-quarter to one-half their original volume. By compression into bricks the volume can be decreased in some cases to one-tenth or less the original volume of the fresh material. The small bulk and weight of dehydrated foods effect a saving in transportation and storage costs.

If properly disinfected or sterilized to destroy insects and packed in insect-proof containers, dehydrated foods will keep for very long periods of time. The writer has recently used dried soup vegetables said to have been dehydrated fifteen years ago. Vegetables dehydrated for use of the British Army in South Africa were in one instance stored in paraffine-sealed barrels at the end of the Boer War. At the outbreak of the European

war, fifteen years later, these barrels were opened, the contents found good and the vegetables used by the British forces. This instance has been reported by Prescott and Sweet.

Canned foods are much more bulky than dehydrated products and more costly to the consumer. For example, it has been stated that a case of canned tomatoes costing \$2.60 in California costs \$7 when delivered to Havre, France. The same quantity of tomatoes dried and selling at 26c. per lb. in California would cost, delivered in Havre, 40.5c. per lb., equivalent to \$1.22 a case, since a case of tomatoes contains about 45 lb. of vegetables and tomatoes dry in the ratio of about 15 lb. of fresh to 1 lb. dry.

Table I, compiled from data published by Prescott and Sweet,¹ summarizes the relation between the weight of dried and canned products from one ton of fresh fruits and vegetables.

TABLE I. WEIGHT OF ONE TON OF VARIOUS FRUITS AND VEGETABLES CANNED AND DRIED

Material	Weight Canned and Boxed, Lb.	Weight Dried, Lb.
Corn.....	1,426	465
Peas.....	4,291	350
String beans.....	3,832	200
Tomatoes.....	1,763	125
Pumpkins.....	2,146	200
Sweet potatoes.....	2,250	513
Cabbages.....	2,400	215
Apples.....	2,640	200-300
Peaches.....	2,850	300-400
Apricots.....	2,850	300-400
Pears.....	2,850	400-570

Dehydrated foods are of "net food value." That is there is no waste in paring or trimming or waste in discarding sirup or brine as is the case with fresh and canned products. The usual labor involved in preparing fresh vegetables for cooking is eliminated for the housewife. All that she need do is to soak the vegetables several hours in water and they are ready for cooking.

However, the principal argument advanced by housewives against dehydrated foods is the fact that they must be soaked in water before cooking. Dehydrator operators are now attempting to develop methods of drying that will permit cooking of the dried products without preliminary soaking. Considerable progress has been made upon this problem.

DEHYDRATION DEFINED

There is considerable confusion regarding the proper terminology for dried products. Manufacturers of equipment used for drying foods almost universally style their machines "dehydrators" and speak of the process as "dehydration." The producers of dried fruits and vegetables use the terms dehydration, evaporation and desiccation. It is probable that "dehydration" is the term most commonly used.

A committee² of representative producers, investigators and dealers in dehydrated products in California adopted the following recommendations:

1. That "drying" be considered the general term applying to all methods.

2. That "sun drying" be used to designate the drying of fruits by the sun's heat.

¹"Commercial Dehydration: A Factor in the Solution of the International Food Problem," by S. C. Prescott and L. D. Sweet; *Annals of the American Academy of Political and Social Science*, May, 1919, No. 1294.

²Committee consisting of A. W. Christie, University of California; P. F. Nichols, U. S. Department of Agriculture, Division of Dehydration Investigations; F. C. Simonds of E. C. Horst Co.; E. W. Sheehan, dealer in dried fruits; H. C. Rowley, Editor *California Fruit News*.

3. That "evaporation" and "dehydration" be considered of equal value in designating the drying of foods by artificially produced heat.

Prof. S. C. Prescott, former chief of the Division of Dehydration Investigations of the U. S. Department of Agriculture, prefers to give modern dehydration a meaning somewhat different than that of evaporation. He considers that dehydration is a more carefully controlled process and results in a superior dried article to that produced by evaporation. His definition follows: "When we speak of 'modern' dehydration we mean foods which either with or without previous treatment have been subjected to the action of carefully regulated currents of air in which the temperature and humidity are both properly controlled, a process which results in the food gradually losing water, but without giving up its color or flavor or having its cellular structure injured."

The writer believes that the word dehydration will in time displace in popular favor the word evaporation, judging from the marked present tendency.

Many of the processes used in dehydration are based upon the results of empirical experiments, but there are certain underlying fundamental principles which afford a rational basis for study of the subject.

HEAT EFFICIENCY

Dehydration involves the change of water from the liquid to the vapor state. This change requires the expenditure of a definite amount of heat, which is about 965 B.t.u. per pound of water evaporated at 212 deg. F.

FIG. 2. STACK EVAPORATOR

and 1,102 B.t.u. at 60 deg. F. From 50 to 75 B.t.u. must be added for each pound of fruit to account for heating the fruit from room temperature to the temperature used in the evaporator. The fuel efficiency of an evaporator can be judged by its approach to the theoretical minimum in its use of heat. We may take this minimum as approximately 1,075 B.t.u. For field purposes A. W. Christie and the writer use the following formula for arriving at an approximate measure of the efficiency of evaporators:

$$E = \frac{F - D \times 1075}{G \times 135000}$$

In this formula

E = fuel efficiency of the evaporator.

F = pounds of fresh fruit placed in the evaporator during the test.

G = gallons of fuel oil used during the test with an assumed calorific value of 135,000 B.t.u. per gal.

D = pounds of dry fruit removed from the evaporator during the test.

Most evaporators tested show an efficiency of less than 50 per cent. An efficiency of 40 per cent is considered good. One reason for this relatively low efficiency is found in the fact that the air must be allowed to leave the evaporator from 20 to 60 deg. F. above the outside air—e.g., air will often be taken into the furnace room at 80 deg. F., then heated to 165 deg. F., used in drying and leave the evaporator at 110 deg. F. It has been raised 85 deg. F. and the air still retains unused 30 deg. F. of the original rise in temperature as it leaves the evaporator.

Many evaporator designers fail to take into account these facts and equip their plants with too small an air-heating system.

AREA OF HEATING SYSTEM

If air is to be heated by steam coils or furnace pipes the total area of the heating surface required may be arrived at by means of the following formula.³

$$H = \frac{Cg}{tm(2 + 10\sqrt{c})}$$

where

H = heating surface in square meters.

tm = mean difference in temperature of the surface and air.

c = velocity in meters per second.

Cg = calories per hour required.

The heating system is more efficient the greater the difference in temperature tm .

The heat transfer varies with the square root of the air velocity—that is, the coefficient of heat transmission is

$$K = 2 + 10\sqrt{c}$$

where c = velocity of the air.

The area of the heating system must be large enough for the coldest weather of the drying season and should allow for a generous safety factor in addition.

VOLUME OF AIR REQUIRED

Air is preferred for dehydration purposes to the use of directly applied heat because overheating of the product is easily avoided; air is convenient to use; equipment for its use is cheap and it permits of easy regulation of the rate of drying and other conditions. It performs two functions in the dehydrator. It conveys heat to the material to be dried, thereby causing evaporation of the moisture, and secondly, it carries away this moisture.

The air must leave the evaporator at a high enough temperature to hold all of the moisture absorbed by it during its passage through the evaporator. Therefore there is a limit to the temperature drop in the evaporator, and for the same reason a limit to the fuel efficiency attainable under usual drying conditions. On hot summer days it is possible to obtain rapid drying by means of a blast of air not artificially heated, or such air may be artificially heated a few degrees only before use. In such cases use is made of the sun's heat, and any

³E. Hausbrand, "Drying by Means of Air and Steam," translated by Wright and published by Scott Greenwood & Co.

calculation of fuel efficiency would have to take this fact into account.

The capacity of air to take up water vapor increases rapidly as the temperature rises. The moisture-absorbing power is approximately doubled by each 27 deg. F. rise in temperature. For example, at 128 deg. F. 350 cu.ft. of air will contain at saturation about 2 lb. of water vapor and at 155 deg. F. about 4 lb. Therefore in calculating the volume of air necessary to carry away from the evaporator the liberated moisture it is necessary to take into account its temperature.

In designing an evaporator, however, the volume of air necessary is not determined by the amount needed to carry away the liberated moisture, but rather by the volume necessary to convey sufficient heat to the product to be dried to cause the desired rapidity of evaporation, because a much larger volume of air is required to furnish the necessary B.t.u. than is required for removal of moisture. For example, at drying temperatures in most common use about 63,000 cu.ft. of air dropping 1 deg. Fahrenheit is required to furnish heat to evaporate 1 lb. of water. Under average conditions the temperature drop will be about 50 deg. F., or the amount of air required to evaporate each pound of water will be $63,000 \div 50 = 1,260$ cu.ft. Since air expands upon heating, larger volumes are required for each 1 deg. F. drop at higher than at lower temperatures.

An evaporator, holding five tons of fresh fruit, which must be dried to one-fifth its original weight in a drying time of fifteen hours, under a temperature drop of 50 deg. F. for the air used, would require an air flow of $\frac{8,000 \times 63,000}{15 \times 50 \times 60} = 11,200$ cu.ft. per minute, since the amount of water to be removed is 8,000 lb.

Experience demonstrates that this amount of air is a minimum for the conditions cited.

EFFECT OF HUMIDITY

For evaporation of water from a free surface the rate of evaporation varies inversely with the relative humidity of the air. This rule does not always hold for the evaporation of water from fruits or vegetables, because of the tendency of some products to "case-harden." Case-hardening is a toughening of the surface—i.e., formation of a semi-impervious film—and greatly retards the rate of evaporation. Case-hardening is caused by the water evaporating more rapidly from the surface than it can be replaced by diffusion from the tissues. It is a result of use of air of too low relative humidity and can be corrected by increase of the relative humidity to the point where diffusion to the surface keeps pace with evaporation from the surface. Pears and potatoes are notable examples of products which case-harden badly. Control of humidity in drying is, therefore, of very great importance and is one of the fundamental principles which are urgently in need of further investigation. Preliminary experiments indicate that the use of air of relatively high humidity (30 to 50 per cent) has very much wider application than was formerly supposed.

AIR VELOCITY

Other things being equal, the rate of evaporation of water from a free surface varies directly in proportion to the rate of application of heat. Since the transfer of heat from air to the material to be dried varies with the square root of the velocity of the air, then the rate

of evaporation should vary in like ratio, that is, in proportion to the square root of the air velocity.

There is a practical limit to the air velocity to be used in practice because of rapid increase of static pressure at high velocities. According to Hausbrand¹ a velocity of 1,150 ft. per minute over the drying trays and of 570 in flues between the fan and drying tunnel should not be exceeded. Our own observations confirm Hausbrand's recommendations.

Less air, and therefore a lower velocity, is required at higher temperatures than at lower temperatures. Thus at 158 deg. F. and 122 deg. F. the relative volumes of air required for the evaporation are in the ratio 5,775 : 9,809 if the outside air is at 58 deg. F. Some evaporators tested by the writer are capable of delivering an air velocity of 900 ft. per minute across the drying trays, but the usual flow is less than 400 ft. per minute. The writer would recommend a velocity 700 to 1,000 ft. per minute.

RECIRCULATION

Since less than 25 per cent as much air is required to carry away evaporated moisture as is necessary to furnish the necessary heat units, it is, theoretically at least, economical to return at least 75 per cent of the spent air to the heating chamber, reheat it and use it again. This has been proved in commercial operation to be good practice. A large flue above or below or beside the drying tunnel can be used to return the air, and air outlets and intakes can be adjusted to maintain the desired ratio of intake to outlet air.

Where case-hardening is encountered, recirculation affords one means of increasing the humidity of the air.

The return flue should be large and the air velocity therein should not exceed 500 ft. per minute.

CRITICAL TEMPERATURES

Although high temperatures of drying give more rapid drying and more efficient use of fuel, there is a temperature for each product either at the beginning or the end of the drying period above which rapid breaking down of the tissues occur or caramelization takes place. We may term this maximum temperature as the critical temperature for the product in question. Caramelization and injury to flavor are more apt to occur near the end of the drying period. Freshly cut apples, or peaches or fresh grapes will withstand very satisfactorily temperatures of at least 195 deg. F., but near the end of the drying period, when the moisture content is low, caramelization will occur rapidly at 175 deg. F. For most fruits a finishing temperature above 150 deg. F. should not be used. Dried vegetables "come back" or "refresh"—that is, reabsorb water more rapidly and return to the more nearly the fresh weight and appearance—if dried at temperatures below 150 deg. F. than if dried at 160 to 165 deg. F.

Higher air velocities and lower drying temperatures will improve the quality of all dehydrated products without lengthening the drying time. These changes are badly needed in many plants.

TYPES OF DEHYDRATORS

There are in use on the Pacific Coast two important types of air current dehydrators. In one of these the heated air rises naturally between and across the pieces of product to be dried. In the other the air by means

¹E. Hausbrand, "Drying by Means of Air and Steam"; Longmans, Green & Co.

of a fan is blown or drawn across or between the pieces of material to be dried.

There are many forms of each type. The Oregon tunnel is the most important form of natural draft evaporator in use on Pacific Coast. One form of Oregon tunnel consists of a concrete or brick furnace room about 18 x 10 ft. in size and about 10 to 12 ft. high, surmounted by several sloping tunnels each about 3 x 5 x 20 ft. in size. The furnace room contains two wood burning furnaces and about 35 ft. of 12 or 14 in. sheet metal pipe. The air is admitted at the base of furnace room walls; is heated by contact with the furnaces and pipes, and rises through the tunnel and across the trays to a ventilator at the upper end of the tunnel.

The stack evaporator consists of a cabinet containing trays set over a furnace room similar to that used for the Oregon tunnel. The air rises through the trays.

The apple kiln form of evaporator consists of a grated floor above a furnace room.

Any of these three forms may be equipped with a fan and the air flow thereby increased, but it has been found much more satisfactory to construct longer and nearly horizontal tunnels through which a blast of heated air is passed across the trays or conveyor of material to be dried. This form permits of recirculation of the air and accurate control of temperature and humidity. To date, the car and tray system of handling the drying fruit or vegetables has proved more satisfactory than the endless metal cloth or belt conveyor system, because of waste of space, sticking of dried material and non-uniformity of drying in the latter.

Many patents have been issued for evaporators and attachments. One man holds a patent upon the use of drying temperatures between 125 and 156 deg. F. Everyone who dehydrates fruit is infringing on his patent. Another holds a patent for drying by means of air drawn across the product to be dried. Infringements are numerous. A few patent suits would clear the situation.

The writer prefers the tunnel type of drier, recirculating air flow, suction fan, and car and tray system. It has proved much more efficient than the natural draft types by actual test.

RESULTS OF EXPERIMENTS

Very important results have been obtained by investigators of the U. S. Department of Agriculture, the state experiment stations, and commercial engineers and chemists. All of these cannot be enumerated here. A few typical results only will be offered.

As before intimated, the horizontal (or nearly horizontal) blast, tunnel type of drier with a recirculation system has proved more efficient and more economical of labor than the natural draft types.

High relative humidity of the air used in drying has been found necessary for products which case-harden—e.g., for pears, potatoes, tomatoes, large prunes and peaches. Most vegetables must be dried to a very low moisture content (less than 8 per cent) to prevent considerable changes in flavor and color.

Vacuum fumigation with CS₂ or heating to 145 deg. F. is effective against insect eggs. Not only the product but also the container (carton, box or can) should be treated, as the latter often contains eggs of the Indian meal moth, the most serious pest to dehydrated products. Low moisture content discourages their growth. Storage at 32 deg. F. will destroy insects and eggs.

Moderate temperatures (below 150 deg. F., preferably below 140 deg. F.) give the best products.

Static pressure (air resistance) has been greatly underestimated by many builders of dehydrators. Tests have shown that flues must be large and sharp angles in flues or tunnels avoided.

Higher velocity of air than is now in common use has proved economical and desirable. A velocity of 800 ft. per minute is recommended.

Blanching (partial precooking) of most vegetables has been shown to be desirable, because it hastens drying, destroys enzymes which would otherwise cause darkening and loss of flavor in the dried product, and because blanching improves and "sets" the color.

Very little sulphuring before drying is necessary for fruits to be dehydrated—much less than for sun-drying. Immersion in dilute salt solution still further reduces the length of sulphuring.

Dipping grapes in boiling dilute lye for a few seconds cracks the skins and shortens the drying period to half or quarter the time required for undipped grapes.

Wine grapes have been dehydrated in enormous quantities in California. (For the preparation of home-made "grape juice"? Draw your own conclusions!) Tests have shown that such raisins may be stemmed, seeded and used for making pies, puddings, etc.

The antiscorbutic value of dehydrated vegetables, especially spinach, is being studied by several investigators. Definite statements on this point would be premature at this time.

Canadian Gas Industry in 1918

The Canadian Bureau of Statistics has just issued an account of the illuminating and fuel gas industry in 1918, being advance sheets of Chemical and Allied Products of Canada in 1918.

There were thirty-eight plants in operation during the year, representing a capital investment for lands, buildings and equipment of \$23,577,224, and employing 1,932 persons at an average wage of \$957 per year. Five kinds of gas were manufactured—namely, straight coal gas and carburetted water gas, which sold at an average of \$1.20 per 1,000 cu.ft.; mixed coal and water gas, and mixed coal and oil gas, which sold at an average price of 85c. per thousand; and acetylene, which brought an average of \$16 per thousand. The average price obtained for the coke produced was \$5.66 per ton. The cost of the coal, oil, calcium carbide and other supplies was \$3,456,396; wages amounted to \$1,849,167; and rent, taxes, upkeep, etc., \$982,306, making a total of \$6,287,869. The sale of gas, coke and byproducts realized \$7,282,147, and the rent and sale of meters, lamps, etc., \$810,826, making a total of \$8,092,937, and showing a profit of \$1,805,104, which amounts to 7½ per cent interest on the capital investment.

Twenty of the thirty-eight plants are situated in Ontario, eight in Manitoba, four in Saskatchewan, three in British Columbia, two in Quebec and one in Nova Scotia. It is a little curious that the principal coal-producing provinces of the Dominion—Nova Scotia, Alberta, and British Columbia—should have only four plants among them, while Ontario, Manitoba and Quebec, which produce no coal, have thirty of the thirty-eight plants. The report does not deal with natural gas, which is used extensively in Alberta, Saskatchewan and Ontario, and in smaller quantities in New Brunswick.

Water-Cooled Acid Chambers Adopted in England

Description of the Mills-Packard Water-Cooled Sulphuric Acid Chambers—Seven Years' Industrial Expansion—Design of the Frustum Chamber—Lead, Steel and Cooling Water Used—Economic Advantages Obtained

By ANDREW M. FAIRLIE*

THE first acid chambers of the Mills-Packard type¹ were built for Edward Packard & Co. at Bramford, near Ipswich, England, in the year 1914. There were two of these chambers, built as replacement of part of an old plant, and they have a rectangular chamber of the ordinary type operating in conjunction with them. However, before connecting these two new chambers to the old rectangular chamber, they were operated for some time by themselves, as an experiment, which proved so successful that it led to the construction of similar chambers at other plants. In 1916 twenty-four chambers of this type were built at eight different plants, all in England, for six different companies. Of these eight plants, three had these chambers exclusively and five had rectangular chambers of the ordinary type in conjunction. In 1917 eighteen Mills-Packard chambers were built, at seven different plants for five different companies, all in England. In 1918 only nine of these chambers were erected, and these were for three different companies, all in England, making a total, up to the close of 1918, of fifty-three Mills-Packard chambers, built or under construction.

While the expansion of the invention had proceeded quite rapidly in England, the war had interfered with its development in foreign countries. The first installation of these chambers outside of the British Isles was at Auckland, New Zealand, where a plant of eight chambers was built in 1918-19. During 1920, in addition to nineteen chambers built at four different plants in England, sixteen of the chambers were erected for two different companies in France, and fourteen for two different companies in Italy—a total of forty-nine chambers for the year 1920, of which all but seven were still under construction at the close of the year. P. Spence & Sons of Farnworth, England, have this year (1921) constructed one additional chamber. Altogether, since 1914 a total of 111 Mills-Packard chambers have been installed or contracted for, located at twenty-seven different plants, and built for twenty-two different companies in four different countries.

OPERATION OF COOLING EFFECT

The invention of this water-cooled chamber was due to the observation of a very common occurrence. In Great Britain it had for many years been the custom to have no building inclosing the acid chambers. A heavy rain in the summer time, following a period of heat, has a marked effect on such chambers, unprotected by so much as a roof, and the cooling of the atmosphere, combined with the effect of the cool rain

flowing over the chamber sides, causes a sudden drop in chamber temperatures through the plant, with much easier operation of the process and evidence of excess of nitrous gas within the chambers, which excess could have been saved had allowance been made for the effect of the rain. Mills and Packard had observed this and wondered why water applied continuously to the outside of the chamber curtains might not increase the production capacity of a plant, or reduce the niter consumption, or both. This thought led to the necessity for a chamber of such design as would be appropriate for the application of water on the outside, and the new chamber was the outcome.

DESIGN OF THE CHAMBER

The Mills-Packard chamber is formed in the shape of the frustum of a cone, with either a raised or slightly dished top. The curtains are supported by either wood or steel columns, but steel is preferred. The bottoms of the curtains dip into the acid contained in a lead pan, forming the familiar liquid seal. Fig. 1 shows respectively the elevation, sectional plan and sectional elevation of this type of chamber.

FIG. 1. ELEVATIONS AND SECTIONAL PLAN OF MILLS-PACKARD CHAMBER

*Consulting Chemical Engineer, Atlanta, Ga.

¹The Mills-Packard patented water-cooled sulphuric acid chamber is the invention of Willie George Mills and Charles Turner Packard, both of Ipswich, County of Suffolk, England. The invention is protected in the United States by U. S. Pats. 1,112,546 (Oct. 6, 1914), 1,312,741 and 1,312,742 (Aug. 12, 1919), and is owned by the firm of Packards & James Fison (Thetford), Ltd., Ipswich, England.

Referring to Fig. 1, it will be noted that the total height of the chamber curtains or walls is divided into five sections, and that at the bottom of each section there is a lead trough completely encircling the chamber. While Fig. 1 shows the chamber walls divided into five sections by five lead troughs, it may be explained that the figure is a drawing of the smallest size chamber and that the larger sizes have a larger number of lead troughs, dividing the chamber walls into a greater number of water-cooled sections. The detail of the lead trough is shown in Fig. 2, an elevation and a section reproduced from the patent specification.²

In Fig. 2 a lead gutter 8 is burned to the lead curtain 1 at the bottom of each lead trough 7, and both gutter and trough completely encircle the chamber. The cooling water flowing down the chamber side is collected in the trough 7, from which it flows, through hole 6, into gutter 8, and then escapes from gutter 8 through the serrated notches at the upper outer edge 9, to flow again down the chamber sides to the next trough below. The lead strap hanging vertically in front of the hole 6 is to prevent splashing of water.

MATERIALS REQUIRED

These chambers have been built in three sizes, of 7,330, 11,890 and 18,750 cu.ft. capacity each, respectively. The smallest size (7,330 cu.ft.) is 20 ft. in diameter at the base and 10 ft. in diameter at the top and is 40 ft. high. The total weight of lead required for such a chamber, including pan, gas connections, etc., is approximately 12.75 long tons, and the total weight of steel is approximately 5.5 long tons. The storage capacity of the pan of such a chamber is 22.4 tons of chamber acid. The quantity of cooling water required is 250 gal. per hour per chamber.

A larger chamber (11,890 cu.ft. capacity) is 47 ft. high and has a diameter of 23.5 ft. at the base and 11.75 ft. at the top. This chamber requires approximately a total of 8.25 long tons of steel and 19.25 long tons of lead, using throughout lead weighing 7 lb. per sq.ft. The quantity of cooling water required for such a chamber is 350 gal. per hour.

Only one plant consisting of chambers of the largest size (18,750 cu.ft.) has ever been built. That plant was erected at Auckland, New Zealand. A chamber of this largest size requires approximately 23 long tons of lead.

²U. S. Pat. 1,312,741.

The tonnage of steel for such a chamber is not known, as the chambers at Auckland had timber supports. The weights given here for the lead required for the three sizes of chambers do not include the lead in false bottoms. If false bottoms are installed, the lead requirements given would be increased by the following weights: For the smallest chamber, 1.1 tons; for the medium chamber, 1.45 tons, and for the largest chamber, 1.6 tons. False bottoms have not been installed except where the platform has been of steel construction. The water used for cooling the outside of the chambers should be reasonably clean, as foreign matter may interfere with the equal distribution of the water

FIG. 2. ELEVATION AND SECTION OF LEAD TROUGH

over the chamber sides, or muddy water may leave a deposit on the lead. Where the cooling water is subject to rapid growth of algæ, the trouble can be eliminated by treatment with a small quantity of copper sulphate. In cleaning the gutters or troughs, care must be taken not to pull them out of shape.

ECONOMIC ADVANTAGES OBTAINED

The advantages claimed for these chambers are:

1. The chamber space required per unit of sulphur burned is reduced to from one-half to one-third the usual space.
2. A very material saving in cost of chamber construction per unit of capacity for making acid. The reduction in cost of chamber construction is said to be from 30 to 40 per cent.
3. A substantial saving in ground space per unit of production capacity.
4. Longer life of the lead chambers.
5. Usually no building is required for housing the chambers.
6. Niter consumption, per unit of sulphur made into acid, is no higher than with the ordinary type of chamber.

7. Feasibility of combining one or more Mills-Packard chambers with rectangular chambers of existing plants, or with tower systems, to increase production capacity at small construction cost.

The principal one of these advantages is the reduction in initial cost of plant for producing a given quantity of acid, brought about by the greatly diminished chamber space required per unit of acid made. Actual operating results for plants composed of these chambers exclusively show only 3.5 to 4.5 cu.ft. of chamber space per pound of sulphur burned per twenty-four hours. Built as an adjunct to the rectangular chambers of an old plant, these water-cooled chambers are effective in reducing the total chamber space required.

Operated at a rate of 3.5 to 4.5 cu.ft. per pound sulphur per twenty-four hours, the niter consumption is stated to be no greater than in the ordinary plant employing 8 to 10 cu.ft. per pound of sulphur. Actual operat-

ing results show a niter consumption of from 3 to 4 per cent, based on the sulphur burned. It is possible if a Mills-Packard plant were operated at a less intense rate—at a rate, for instance, of 6 to 8 cu.ft. per pound of sulphur in twenty-four hours—that considerable economy in niter consumption might result. No data are available on this point, however, as the demand for acid has been so great that Mills-Packard chambers have been run at the intensive rate of about 3.5 to 4.5 cu.ft. of space per pound of sulphur per day.

WIND PROTECTION SOMETIMES REQUIRED

A view is shown in Fig. 3 of an installation of nine Mills-Packard acid chambers. It is the customary practice, in erecting these chambers, to leave them unhoused. In exceptionally exposed places, however, a light wind screen, to protect the chambers about half way up, is advisable, and such a screen is generally recommended for the chambers of the larger sizes, if the location is at all exposed. With timber framework, complete housing would be considered necessary in some climates, and for this reason steel framework is preferred. The chambers at Auckland, New Zealand, having timber framework, are completely housed, and this is the only fully housed Mills-Packard chamber in existence at the present time. In the case of the nine chambers of the medium size erected for P. Spence & Sons, England, a

FIG. 3. VIEW OF NINE-CHAMBER MILLS-PACKARD PLANT

wind screen of light construction about 25 ft. high was built around the chambers.

SOME TYPICAL DATA

The operation of this type of chamber, it is claimed, involves no greater supervision than the operation of chambers of the ordinary type. The following table, quoted from a letter dated May 25, 1920, from an English acid manufacturer, gives the chamber temperature for each of six of a set of Mills-Packard chambers of the intermediate size (47 ft. high):

Chamber No.	Temp. Deg. C.	Chamber No.	Temp. Deg. C.
1	77-84	4	50-60
2	62-72	5	30-40
3	60-70	6	20-30

The same manufacturer quoted for these chambers a total chamber space used of 3.66 cu.ft. per pound sulphur burned per twenty-four hours, with a niter consumption of 3.62 per cent, based on sulphur burned, as average

figures for March and April. This manufacturer allowed the chamber drips, in the front chamber, to run as high as 124-132 deg. Tw. (55-57 deg. Bé.). The Packard company, however, recommend chamber drips of not more than 100-115 deg. Tw. (48-53 deg. Bé.), which corresponds to the usual practice in this country.

The maintenance cost for these chambers is said to be very light. As some of the chambers have been erected for seven years, it is possible to get some idea as to upkeep expense. A letter from E. Packard & Co. states that repairs to the lead have been limited, so far as experience at their own plant goes, to a few cracks where the straps were burned to the curtains, and these cracks were easily repaired. Of two samples of lead taken from the curtains of a chamber after five years one showed a loss of 1.89 per cent and the other no loss.

One chamber has been erected in connection with an Opl tower plant in England, and the same company has two Mills-Packard chambers operating in connection with rectangular chambers of the ordinary type. This firm is now building six additional Mills-Packard chambers.

So far no Mills-Packard chamber has been erected in the United States. It has already become quite popular in England, however, and last year the popularity began to spread into continental Europe, indicating sound foundation for the peculiar merits claimed for the external water-cooling.

Legal Notes

BY WELLINGTON GUSTIN

U. S. Supreme Court Holds Burchenal Patent Void for Anticipation by the Normann Process

The decision of the Supreme Court of the United States in the patent case between the Berlin Mills Co. and the Procter & Gamble Co. (41 S. C., 75) presents some interesting facts. The suit was brought by the latter company for infringement of the patent of John J. Burchenal for a food product, issued in 1915, No. 1,135,351, and assigned to it. The District Court held the patent void for lack of invention, but the Circuit Court of Appeals held the patent valid and infringed. (167 C. C. A., 295.)

The patent relates to a product consisting of vegetable oil partially hydrogenized to a homogeneous whitish yellowish product. The record in the case discloses that the making of lard substitutes has been accomplished by mixing melted fat with vegetable oils containing glycerides—olein, linolin and stearin. The hydrogenation, or hardening process, has the effect of increasing the proportion of the solid glycerides of high saturation. Stearin is called a saturated glyceride, for the reason "that there are present in the molecule as many hydrogen atoms as possibly can be joined to the carbon atoms." Linolin and olein are called unsaturated glycerides, and can be converted by the addition of hydrogen into hardened glycerides.

PURPOSES SET OUT BY INVENTOR

The purposes set out and the inventor's intention are as follows: "The special object of the invention is to provide a new food product for a shortening in cook-

ing, in which the liability to become rancid is minimized, and in which the components of such vegetable oils which are inferior and detrimental to use as such a food product have been to a large extent converted into a higher and more wholesome form. All such vegetable oils contain glycerides of unsaturated fatty acids and, among these, notable quantities of fatty glycerides of lower saturation than olein. It is the presence of these glycerides of lower saturation that seriously affects the rancidity, which oxidation weakens the fat at the point of absorption at the double bonds, and these glycerides of lesser saturation readily absorb oxygen from the air at ordinary temperatures, while the more highly saturated glycerides, as olein, only absorb oxygen at elevated temperatures. It is evident, therefore, that oils or fats containing notable quantities of glycerides of linolic acid, or of lesser saturation, are distinctly inferior as an edible product to those containing a minimum of these glycerides with a larger per cent of olein. On the other hand, while it is important to get rid of the readily oxidizable glycerides of lower saturation, it is also important not to supply too large a per cent of fully saturated glycerides. . . . Oil, liquid at the ordinary temperatures, does not make the best shortening because the oil remains liquid, keeping the food in a soggy condition, and the oil will even settle to the under part of the cooked product and soil the cloth, paper or whatever it may come in contact with. Moreover, fats of a melting point above the temperature of the human body, 98 deg. F., are not so digestible as fats which are liquid at this point, or which have a melting point below 98 deg. F. It is therefore my object in the preparation of my new lardlike composition and food product, and in preparing same from cottonseed oil, to change the chemical composition of the oil to obtain a product with a high percentage of olein, a low percentage of linolin and the lesser saturated fats, and with only sufficient stearin to make the product congeal at ordinary temperatures.

PROCESS AS DESCRIBED IN THE PATENT

"In manufacturing this product cottonseed or other vegetable oil is caused to absorb chemically a limited amount of hydrogen by reacting on the oil with hydrogen in the presence of a catalytic agent and at an elevated temperature. The oil is preferably agitated in a closed vessel in the presence of an atmosphere of compressed hydrogen, a catalyzer of finely divided nickel carried by kieselguhr being maintained in suspension in the oil and its temperature being raised to about 155 deg. C.

"According to the present invention the amount of hydrogen absorbed is carefully regulated and limited. In practice, the operation is stopped when the oil has been converted into a product which cools to a white or yellowish semi-solid more closely resembling lard than do the commercial mixtures of cottonseed oil and animal oleostearin, while in many respects the product is superior to the best leaf lard as a shortening. It is not so liable to become rancid, and the product can be heated to a considerably higher temperature than lard without smoking or burning. . . . The high temperature to which my product can be raised without smoking or burning makes the product ideal for frying, inasmuch as a crust forms almost instantly on the food fried, which prevents any absorption of the shortening. A lardlike product thus prepared from cottonseed oil has a saponification value of about 195

and an iodine value ranging from about 55 to about 80. The product having an iodine value of 55 has a titer of about 42 deg. and a melting point of about 40 deg. C., that having an iodine value of 80 has a titer of about 35 deg. and a melting point of about 33 deg. C. While but partially hydrogenized, containing from about 1.5 per cent to 2.5 per cent of additional hydrogen more than in the non-hydrogenized material, it shows no free cottonseed oil when subjected to the Halphen test, thereby differing from all commercial lard substitutes containing this oil. It contains from 20 to 25 per cent of fully saturated glycerides, from 5 to 10 per cent linolin, and from 65 to 75 per cent olein, and an average of a number of samples gives 23 per cent of saturated fats, 7.5 per cent linolin and 69.5 per cent olein, while the cottonseed oil before treatment contained 17 per cent saturated fats, 37 per cent linolin and 46 per cent olein. It will thus be seen that I have produced an ideal food product which is high in olein, low in linolin and lesser saturated fats, and with only enough stearin to make the product congeal at ordinary temperatures."

TWO BROAD CLAIMS INVOLVED

There are two broad claims of the patent involved in this case. They are:

(1) "A homogeneous lardlike food product, consisting of an incompletely hydrogenized vegetable oil."

(2) "A homogeneous lardlike food product, consisting of incompletely hydrogenized cottonseed oil."

It was necessary for the Supreme Court of the United States to consider what was theretofore known and disclosed in the act. Burchenal, the patentee, was not a chemist, it is said, and was the general manager of the Procter & Gamble Co. One Edwin C. Kayser, who had been in the employ of Crossfield & Son, an English firm, and familiar with the Normann process, to be considered hereinafter, came to this country in 1907 and entered into a contract with Mr. Burchenal whereby an experimental plant was erected at the Procter & Gamble works for hydrogenating oil.

It was the contention of the Procter & Gamble Co. that Burchenal was the first to originate and develop the process involved. The District Court found that he, in fact, invented nothing, and that all that was real invention came from Kayser. But, said the court, considering for the purpose of this discussion that the thought occurred to Burchenal, which he developed in the production of a food product, the primary question presented is whether what Burchenal accomplished amounted to invention within the meaning and protection of the patent law.

This was not claimed to be a process patent, but a product patent of a new and useful thing within the meaning of the patent law. Said the court, if this product were the result of mechanical improvement only, when viewed in the light of that which was previously disclosed and open to public use, the step in advance being only that which one skilled in the art might well make, without the exercise of the originating or inventing faculty, then the achievement is not within the protection of the patent law.

THE NORMANN PATENT

The English patent to Normann of October, 1903, disclosed to the world the process of converting unsaturated fatty acids or their glycerides into saturated compounds.

One expert witness gave his views on the Normann process as follows, in part:

"Dr. Normann discovered, and set forth in the patent, that unsaturated acids or unsaturated oils by the action of hydrogen in the presence of finely divided nickel may be converted into corresponding saturated compounds. He says, for instance, if fine nickel powder obtained by reduction in a current of hydrogen is added to chemically pure oleic acid, then the latter heated over an oil bath, and a strong current of hydrogen is caused to pass through it for a sufficient length of time, the oleic acid may be completely converted into stearic acid."

Dr. Normann himself said:

"By causing actylene, ethylene or benzene vapor in mixture with hydrogen gas to pass over one of the said metals, the said investigators obtained from the unsaturated hydrocarbons saturated hydrocarbons, partly with simultaneous condensation.

"I have found that it is easy to convert by this catalytic method unsaturated fatty acids into saturated acids. This may be effected by causing vapors of fatty acid together with hydrogen to pass over the catalytic metal, which is preferably distributed over a suitable support, such as pumice stone. It is sufficient, however, to expose the fat or the fatty acid in a liquid condition to the action of hydrogen and the catalytic substance.

"For instance, if fine nickel powder, obtained by reduction in a current of hydrogen, is added to chemically pure oleic acid, then the latter heated over an oil bath, and a strong current of hydrogen is caused to pass through it for a sufficient length of time, the oleic acid may be completely converted into stearic acid."

Dr. Normann did not specify in his patent any of the purposes for which his patents are intended, or what these products should be used for. It was said they might be used for any purpose for which fats of that general character could be utilized—as for candles, for soaps or for edible purposes. The court found Normann's process was a practicable one, and may be used for making food products of the kind involved in this case.

WAS NOT INVENTION, SAYS COURT

With the knowledge disclosed in the Normann patent, was it invention to apply the known process to vegetable oils? The record in the case established that it was known before Burchenal took up the subject that a vegetable oil could be changed into a semi-solid, homogeneous substance by a process of hydrogenation arrested before completion, and that it might be edible. This much of the art was public property and open to general use. The product of this process was known and open to public use, says the court, and to supply such products as the patentee has described in the broad claims in suit may have been new and useful, but did not, in the Supreme Court's opinion, rise to the dignity of invention, and is an advance step which would readily occur to one skilled in the art when he was investigating and considering the subject.

Therefore the Supreme Court reversed the decree of the Court of Appeals and the cause was remanded to the District Court with directions to dismiss the bill on the grounds that claims (1) and (2), set out above, were void.

Constitution of Chromium: Tungsten Steels

Recent Japanese Work Throwing Light Upon the Complex Reactions Giving Self-Hardening and Red-Hardness Properties to Modern High-Speed Steels—Edwards' Views on Like Subjects Are Also Briefly Given

HONDA and Murakami¹ have followed these investigations by a series of tests of steels containing both chromium and tungsten to determine the forms in which these two elements exist after normal slow cooling, their effect upon hardening and tempering and changes in the constituents during heating and cooling.

Three series of steels were used:

(1) W and Cr nearly constant at about 18 per cent and 5 per cent respectively, the carbon varying from 0.33 to 1.26 per cent.

(2) W and C nearly constant at about 18 per cent and 0.65 per cent respectively, the chromium varying from 0 to 7.35 per cent.

(3) Cr and C nearly constant at about 5 per cent and 0.65 per cent respectively, the tungsten varying from 0 to 18.8 per cent.

By similar experimental methods as used in their studies of chromium and tungsten steels as described briefly in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 24, pp. 703 and 745, these investigators reached the following conclusions:

1. In steels normally cooled from 900 deg. C. the Ar_2 or Ar_1 transformations occurring at 750 to 700 deg. C. decrease in magnitude almost to suppression. The lowered $Ar_{3,2}$ transformation² becomes conspicuous with increase in carbon from 0.33 to 0.57 per cent. If, however, the carbon content increases beyond 0.85 per cent the normal $Ar_{1,2,3}$ transformation once more begins to manifest itself at the expense of $A'_{3,2}$ and finally again is the only one noticed, occurring at the normal point in a steel containing 1.26 per cent carbon, about 18 per cent tungsten and 5 per cent chromium.

In steels similarly cooled from 1,200 deg. C. transformation Ar_2 of low-carbon steels is partially suppressed in magnitude with increasing carbon content. With carbon greater than 0.57 per cent the normal transformation has disappeared. As carbon content increases the temperature of lowered transformation ($A'_{3,2}$) gradually falls, reaching 100 deg. C. with 1.26 C steel.

2. Chromium in combination with carbon effects the suppression of the Ar_1 transformation, upon which self-hardening depends. With about 0.6 per cent carbon and 18 per cent tungsten 3 per cent of chromium is sufficient to suppress the 700 deg. change, and to effect self-hardening. Higher chromium is only effective in lowering $A'_{3,2}$ if more carbon is added, which agrees with Edwards' conclusions³ to the effect that hardness of hardened steels containing 0.6 per cent carbon and 18 per cent tungsten rapidly increases with the addition of chromium from 0 to 3 per cent, but when this

element is further increased the effect of this latter increase is almost nil.

3. The effect of adding tungsten to these high-speed steels is principally to diminish the maximum temperature at which, during cooling, the lowering of the transformation takes place. Its effect on the lowering or self-hardening property is small, provided chromium and carbon contents are as given for the steels described by Honda and Murakami. Edwards³ found the hardness of hardened steels containing definite proportions of chromium and carbon to be nearly constant as tungsten varied up to 12 per cent, but with further increase the hardness gradually became greater.

4. After normal slow cooling from 900 deg. C. a high-speed steel containing about 18 per cent tungsten, 5 per cent chromium and 0.6 per cent carbon consists of iron dissolving tungstide Fe_2W , free tungstide, tungsten carbide (WC), together with the non-magnetic chromium carbide Cr_4C , all in a free state. These may be represented as follows:

If the steel be heated a little above Ac_1 the carbides dissolve in austenite, but are reprecipitated at the normal Ar_1 point if the maximum temperature does not materially exceed Ac_1 . As the temperature of reheating increases, however, chromium carbide dissociates:

The higher the temperature the more the change proceeds from left to right, the products dissolving in austenite, except remnants of Fe_2W . In normal slow cooling from a high temperature the reverse change takes place to only a small degree, and therefore at room temperature the steel contains the carbides, chromium and part of the tungstide all in solid solution, which condition results in a hardened steel.

If the specimen thus thermally treated be again heated the dissolved carbide gradually separates, and the steel is tempered in two steps at about 400 deg. C. and 700 deg. C. If the specimen is further heated to the Ac_1 point the free carbide dissolves and the reactions given above proceed from right to left, Cr_4C and WC being formed. Hence by cooling from a temperature a little above the Ac_1 point the carbides Cr_4C and WC separate in the Ar_1 range and we thus obtain the normal structure. The same structure can also be obtained by a sufficiently slow cooling from a very high temperature through the range of 700 deg; because the carbides Cr_4C and WC are slowly formed in this range.

This does not agree, however, with the conclusions reached by Edwards³ that the lowered critical point ($A'r$) which occurs in cooling from a high initial temperature is not the cementite change lowered by the presence of tungsten or chromium but a change in a carbide of tungsten which is slowly formed at 1,200

¹Sci. Reports, Tohoku University, vol. 9 (1920), p. 143.

²Called by these authors $A'r_{3,2}$ since they regard it as the superimposed Ar_3 and Ar_2 changes lowered from their position as called for on the Fe: C diagram to 400 deg. C. or less.

³J. Iron & Steel Inst., 1908, No. 2, p. 104.

Fig. 3. P. S. high-speed steel, 3.98 Cr, 13.49 W, 0.67 C. Annealed, etched with acid. $\times 190$.

Fig. 4. Same as Fig. 3, except etched with $K_3Fe(CN)_6$.

Fig. 7. Steel containing 4.85 Cr, 16.01 W, 1.0 C; cooled from melt. Etched with $K_3Fe(CN)_6$.

Fig. 8. Steel containing 4.88 Cr, 9.74 W, 0.55 C; cooled from melt. Etched with $K_3Fe(CN)_6$.

deg. C. The absence of the A'r point in specimens cooled from 1,320 deg. C. was ascribed by him to a double carbide of tungsten and chromium formed at high temperatures and held in solid solution even on very slow cooling. Thus he thinks that chromium in high-speed steels forms a double carbide with tungsten, which if held in solid solution imparts high hardness and resistance to tempering. This line of reasoning cannot yet, however, be considered as a true explanation of the function of chromium in high-speed steels.

5. Self-hardening and resistance to tempering increase with chromium and carbon contents conjointly. Increase in maximum temperature or rate of cooling is also intimately connected with the lowering of the transformations. The specific properties of high-speed steel depend principally upon the quantity of dissolved Cr_3C_2 in iron containing chromium and tungstide.

The fine globules appearing under the microscope in slowly cooled high-speed steels in a pearlitic, sorbitic or even troostitic matrix are considered by many investigators to be double carbides of tungsten and chromium or tungsten carbide, because they are colored black in boiling sodium picrate solution. Some investigators, however, believe them to be tungstide, in which opinion Honda and Murakami concur for the following reasons:

1. They have the same properties for chemical reagents as the tungstide found in carbonless iron-tungsten alloys⁴ (colored black by picrate or a ferricyanide solution, but remain white when etched in acid).

2. In steels of given carbon and chromium contents they increase in quantity with tungsten content.

3. In steels of given and constant tungsten and chromium contents the globules do not increase but rather decrease with increasing carbon.

As an etching reagent for the globules an alkaline solution of potassium ferricyanide (10 g. KOH and 10 g. $K_3Fe(CN)_6$ in 100 c.c. water) was found satisfactory by these Japanese investigators. Immersion in cold solution for fifteen to twenty seconds colors the globules brown to black, leaving the matrix white. The solution of sodium hydroxide and hydrogen peroxide used by Yatsevitch⁵ also colors the globules black in cold solution, but was found to be unstable. It also requires ten to fifteen minutes immersion.

Figs. 1 to 8 inclusive show typical structures obtained by Honda and Murakami in their study of high-speed steels. Figs. 1 to 4 show tungstide globules, white when

⁴See CHEM. & MET. ENG., vol. 24, No. 17, April 27, 1921, p. 746.

⁵Rev. Met., vol. 15 (1918), p. 65.

etched with acid and black when ferricyanide is used, the quantity being greater in the steel of highest tungsten content. Figs. 5 to 8 show the cast structure of various chromium : tungsten steels where the tungstide has segregated in a eutectic form in the primary grain boundaries. This constituent does not increase with carbon and is absent in steels containing less than about 8 per cent tungsten, its quantity being very small in the steel containing 9.74 per cent W shown in Fig. 8.

The action of tungsten, according to Honda and Murakami, when present over 12 per cent, is purely mechanical through the globules of free tungstide, which in a good tool must be uniformly distributed.

Not only are the researches carried on by Honda, Murakami and others of considerable interest but they should react to stimulate further investigation of the fundamentals of the constitution of high-speed tool steels and publication of results obtained. While their various conclusions will be disputed and hypotheses may be successfully overthrown, great credit is due these men in their pioneer work, directed toward the solution of problems involving reactions of great complexity connected with series of steels of the greatest importance.

Electric Furnaces for Melting Non-Ferrous Metals

TESTS on two new types of electric furnaces developed by the General Electric Co. for melting non-ferrous metal show a percentage of metal loss for yellow brass of less than 1.5 per cent and less than 0.75 per cent for red brass. The thermal efficiency is high, and the expense for refractories and electrodes is reduced to a low value.

These furnaces have been designed in two sizes, a 1,500-lb. unit and a 50-lb. unit. Either will melt practically any metal requiring a pouring temperature not exceeding 1,500 deg. C. (2,732 deg. F.).

Both furnaces work on the muffled arc principle, the main difference in construction and design being due to the variation in size and the fact that the 1,500-lb. type is three-phase and the 50-lb. is single-phase. The power factor for both is 0.95 or better.

The 1,500-lb. furnace melts yellow brass, pouring at 1,100 deg. C., with a power consumption not exceeding 270 kw.-hr. per ton, operating twenty-four hours a day, with one heat every hour. This gives a total capacity for the furnace of 18 tons of metal in a 24-hour day. The 50-lb. furnace melts yellow brass, pouring at 1,100 deg. C., at the rate of from 100 to 125 lb. per hour, with a power consumption of from 35 to 40 kw.-hr. per 100 lb. of metal, providing the furnace is up to temperature at the beginning of the run.

The 1,500-lb. furnace forms a balanced and very steady load on a polyphase circuit, and is equipped with electrode regulators which automatically maintain the desired power input. It has a shell built of steel plate, lined with standard fireclay shapes, and having a bulged boiler head bottom. The roof frame is hinged to a bar, the shell at the front of the furnace, the same bar carrying a three-legged cast-iron spider which mounts the electrode-supporting mechanism. This permits the whole top of the furnace to be lifted for inspection or repair of the lining without disturbing the electrodes.

Fig. 1 shows the interior arrangement of the three D-shaped muffles, wearing blocks, cross-electrodes and vertical electrodes, which comprise the heating elements.

As shown, the space in the muffle between the electrode and wearing block and the side of the muffle is filled with crushed graphite to muffle the arc. The triangular space where the cross-electrodes meet in the middle is filled with a mixture of graphite and tar to insure a good electrical connection.

The 50-lb. furnace is constructed on much the same principle except that in this case the hearth is flat, designed to receive standard graphite crucibles. There

FIG. 1. INTERIOR ARRANGEMENT OF 1,500-LB. HEARTH CAPACITY NON-FERROUS MELTING ELECTRIC FURNACE

is also some difference in the electrode and block arrangement, since the furnace is for single-phase operation. A horizontal carbon block, imbedded in crushed graphite, extends across the bottom, carrying a wearing block on each end. Between these wearing blocks are four carborundum bricks which form the hearth. Two graphite electrodes extend through the roof to the wearing blocks, the arcs being smothered in the graphite surrounding the blocks. The electrode regulation is entirely manual. In operation the crucible containing the metal to be melted is set on the carborundum bricks forming the hearth.

The metal is heated by the same action in both furnaces. The current flows from the vertical electrodes through arcs to the crushed graphite and the wearing blocks. These arcs are smothered by the graphite in the muffles, the whole mass becomes heated, forming a heat source of large area and uniform temperature. The heat is radiated to the metal from all directions as well as being absorbed from the muffles and the hearth.

Not the least of the advantages of the electric furnace are those which influence shop conditions for the better. The absence of dirt and the fumes both from the metal and from burning fuel make the shop atmosphere much more bearable; in addition the electric furnace is practically noiseless. Furthermore, there is comparatively little external heat radiation, and the temperature of the foundry is not raised appreciably.

Acid vs. Basic Electric Furnace For the Foundry

BY F. W. BROOKE*

ACID operation should be adopted when

(1) The sulphur in the scrap is and *always will be* less than the sulphur required in any castings you will be required to make.

(2) The phosphorus in the scrap is and *always will be* less than the phosphorus required in any castings you will be required to make.

A prospective purchaser of an electric furnace, in looking over his available scrap supply, often feels he can obtain all the scrap he requires of a sulphur and phosphorus content low enough (say below 0.04 per cent sulphur and phosphorus) to meet his requirements. The scrap market and the freight situation, it has been our experience, only too often upset his calculations, and he is confronted with the problem of having a high-sulphur and phosphorus scrap and a furnace which cannot eliminate these all-important injurious elements. It has often meant one of three things: (a) paying an excessive price for low-sulphur and phosphorus scrap; (b) a shut-down until proper scrap can be obtained; or (c) bad castings and a dissatisfied customer.

Let us assume that the above situation can be satisfactorily met. There is still the subject of requiring a low-sulphur for special occasions, as for instance the making of a specially difficult casting where the foundry has its own particular difficulties and where a low-sulphur steel would be of particular value in helping out the foundry. This can only be done in a basic furnace.

(3) When the range of carbon and silicon contents will always be wide.

(4) When close physical tests have not to be met.

It is much easier to control the carbon, silicon and manganese in the basic furnace, which means that where specifications have to be met the rejections are much less, particularly on physical tests, such as a good relation between the maximum stress and yield point, and a good elongation with a relatively high maximum stress. This is because of the inherent value of an electric furnace for making refined steels of a quality better than the converter steel, the open-hearth steel and at least equal to crucible quality, which is only present in the basic operation.

Refining can be done in the acid furnace to a limited extent, but calls for skillful operation and is not reliable.

(5) When power consumption and rate of operation are of prime importance.

The acid operation gives a better power consumption in the relation of about 100 to 112, because there is practically no refining in the acid operation. It also gives a less refractory cost, as the cost of raw material is less and the repairs are less frequent.

(6) When very small castings are the sole output.

In making all small steel castings, three important points must be kept in view:

(a) Do not have the furnace of too large a capacity—install smaller units and more of them; for instance, where the castings do not exceed 10 to 15 lb. a 1-ton furnace should be the maximum.

(b) "Hot" metal is essential, because of the necessity of pouring into shank ladles where the transfer

losses and the ladle losses are high and because of the number of "pours" required.

(c) It must be easy to hold back the slag and acid slag will keep back and separate more readily.

This does not mean that small castings cannot be made in the basic furnace, but means that in foundries where castings weighing ounces and a maximum of say 25 lb. are to be made, the acid operation is easier and more economical, providing, of course, that the other clauses can be met satisfactorily.

Basic furnaces should be installed for reasons (1) to (4) opposite of those given above, and

(5) When alloy steels are ever to be made in the furnace.

If alloy steels are ever contemplated, a basic furnace is required. Manganese steels, for instance, so often required in the steel foundry industry, can only be economically made in the basic furnace. The use of other elements, particularly chromium, vanadium, etc., can be handled only in the basic furnace, and while the making of alloy steel castings may not be of immediate consideration, their use is becoming more general every day, especially for parts requiring uniform wearing qualities, resistance to shock and resistance to alternating stresses.

(6) When steady load is essential.

A basic furnace invariably has a steadier load than an acid furnace, for two reasons:

(a) Higher secondary voltages are used in the acid to bring about more rapid melting.

(b) The resistance of an acid slag is higher than the resistance of a basic slag, and therefore also requires a higher voltage.

Both of these calling for a higher secondary voltage causes in practice longer arcs and higher surges because the electrode travel cannot pick up as rapidly.

(7) When refining of cast iron is being considered.

Probably the latest field which is making very rapid strides for the electric furnace in the foundry is for the refining of cast iron. This is particularly applicable to the making of engine cylinders, high-pressure valves, piston rings and parts requiring uniform wearing qualities, etc., and the practice now being adopted is to pass the molten pig iron from the cupola through the electric furnace for a refining period of twenty to forty minutes, which gives: (a) A rapid desulphurization. (b) Elimination of occluded gases. (c) An accurate pouring temperature.

These causes will speak for themselves to the progressive foundryman, who in the past on particular work had gone through periods of worry in his: Sulphur in the coke; blowholes; and "hot" metal and "cold" metal.

Only the basic furnace can be considered for this purpose.

In looking over the number of furnaces recently installed in foundries, it must be surprising to find the large percentage of acid installations. These furnaces were only too often installed by foundries that used electricity as a "fuel" and the electric furnace as the melting pot. They sold their product during a time when there was a loud cry for steel castings and when inspection was either entirely missing or at least lenient. The sulphur and phosphorus specifications and physical requirements were seldom met. This does not mean that the acid furnace had not its own field, but decision should be reached after a careful study of all the existing conditions and as many of the future conditions as possible.

*Vice-President, Electric Furnace Construction Co., Philadelphia.

Recent Chemical & Metallurgical Patents

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office Southampton Buildings, Chancery Lane, London, England.

Electrolytic Copper.—Elastic or tempered copper is produced by deposition from a sulphate solution on a cathode rotating at a peripheral speed not less than 1,000 ft. per minute. Hardness may be increased by the use of higher speeds, or by addition of say 0.1 per cent of an organic substance such as glue or gelatine, or of arsenic, preferably to the amount of $\frac{1}{16}$ oz. to 1 gal. of 12 per cent copper sulphate solution containing free sulphuric acid. The arsenic may be added in the form of oxide dissolved in 10 per cent caustic soda solution. (Br. Pat. 154,373; S. O. COWPER-COLES, Sunbury on Thames, Jan. 26, 1921.)

Electric Furnace.—In a furnace having resistance bars, free to expand or contract, arranged in the form of one or more grids above the charge, a slight reduction of pressure is maintained to prevent condensation in the openings through which the bars enter the furnace. The charge may consist of copper, nickel, iron, aluminum, brass or materials to be distilled. As shown, the resistance bars 10, which may be of carbides such as silicon carbide, pass loosely through refractory sleeves 16 in the furnace walls. The furnace may be tilted by worm gear so that parts of the charge may be brought nearer to the resistance. The trunnions may form axles for a pair of large wheels which thus support the furnace. In some forms, a hopper 17 is provided in the middle of the roof and between two parts of the resistance. Above the hopper 17 there may be a preheating chamber 12. A slight suction is produced in the furnace by providing an adjustable vent 14 in the cover of the hopper or of the preheating chamber for the vapors which may pass through the hopper or through outlets 15 in the furnace roof. (Br. Pat. 154,444. A. M. ERICHSEN, Porsgrund, Norway. Jan. 26, 1921.)

Cracking and Purifying Oils.—Hydrocarbon oils are purified or cracked and purified by heating in presence of sodium or other alkali metal or of an alkali amalgam or alloy such as sodium-lead alloy. The oil and metal may be heated in an autoclave and the oil afterward distilled in the presence or not of the metal; the oil vapor may be passed through the molten metal, or the oil may be fractionated or cracked from a still or retort containing the metal. The process may be continuous or intermittent, and the distillation may be carried out at, above or below atmospheric pressure. (Br. Pat. 154,464; N. V. S. KNIBBS, London, Jan. 26, 1921.)

Electrolytic Nickel.—In a cyclic process, nickel is dissolved from ore, matte, or the like to form a solution having an optimum acidity for deposition—i.e., a percentage of free acid between 0.1 and 0.4. The solution is passed in series through the cathode compartments of a number of vats, while a nickel salt solution is passed in series through the anode compartments, the diminution of acidity of the catholyte through electrolysis being compensated for by partial transfusion of the anolyte, which increases in acidity in successive vats. When the acidity of the anolyte has become incompatible with the maintenance of the catholyte acidity below 0.4 per cent, the anolyte is withdrawn and, without concentration, is used for preparing fresh solution to be added to the circulating catholyte. The anolyte may be replenished from the fresh solution or from the catholyte. Each vat preferably contains a number of alter-

nating cathode compartments and insoluble anodes within a single anode compartment, electrolyte being fed in parallel through the cathode compartments of each vat but in series through those of different vats. Diaphragms of clay, wood or paper, or of framed millboard which may be treated with water-glass, are suitable. The catholyte may be at a higher level than the anolyte, so as partly to percolate through the diaphragms. The current density may be 10 amp. per sq.ft. (Br. Pat. 154,471; C. HEBERLEIN, London. Jan. 26, 1921.)

Potassium and Sodium Carbonates.—Technically pure potassium carbonate is obtained by a wet process in which potassium bicarbonate is decomposed with nascent potassium sulphide. The bicarbonate, preferably in granular form, is intimately mixed with finely ground potassium sulphate and barium sulphide and the resulting mixture is added to boiling water. The sulphuretted hydrogen produced is eliminated by boiling or by the passage of steam. The bicarbonate goes into solution with difficulty, but reacts with the nascent potassium sulphide immediately the latter is produced from the barium sulphide. Barium sulphide is regenerated from the precipitated barium sulphate after its removal from the potassium-carbonate solution, from which crystalline or amorphous potassium carbonate may be prepared. By using sodium bicarbonate and sodium sulphate in the place of the corresponding potassium salts, technically pure sodium carbonate may be obtained in a similar manner. (Br. Pat. 154,498; S. LARUM, Brussels. Jan. 26, 1921.)

Aldehyde; Acetic Acid.—Acetylene, air and steam are passed over a catalyst at 300 to 400 deg. C. and the resulting aldehyde and acetic acid are condensed fractionally, or first oxidized completely to acetic acid. The weak aldehyde fraction is used to produce the necessary steam. As catalysts are specified basic metallic salts, particularly vanadates, molybdates and chromates. In an example, basic zinc vanadate is precipitated from alkaline ammonium vanadate solution by zinc chloride and deposited on rubbered pumice, the rubber being then burned off in air. (Br. Pat. 154,579, not yet accepted; A. WOHL, Dantzig. Feb. 2, 1921.)

Refining Oils and Fats.—In refining and removing fatty acids from vegetable, animal and fish oils and fats the oil is heated to 200 to 300 deg. F. by passage through a heat exchanger 2 and an electric heater 3, and is sprayed into a refining tower 5, in which it meets an ascending current of carbon dioxide or of carbon dioxide and nitrogen heated if necessary by a heater 8. The partly refined oil may be circulated by a rotary pump 4 and is discharged through the heat exchanger 2 to a reservoir 27. The carbon dioxide and the vapors pass through a separator 9 to a heat-exchanger 10 and thence, after admixture with steam, in

a jet 11, to a condenser 12. Fatty acids condense and collect in receivers 23, 24. The gases may be scrubbed with oil in a scrubber 14, and are led to a gasholder or are returned through the heat exchangers 19, 10 to the tower 5. Cooling-water passes first through a cooler through which the oil from the scrubber 14 is circulated, then through the condenser 12, and then through the heat exchanger 19. (Br. Pat. 154,514; K. H. VAKIL, Bombay, India. Feb. 2, 1921. See also Pat. 155,020, Feb. 9, 1921.)

Distilling Hydrocarbons, Alcohol, etc.—The condensation of vapors in apparatus for distilling crude mineral oils, volatile hydrocarbons, alcoholic liquids, etc., is utilized to generate steam which may be used for heating or power producing. When distilling liquids with a boiling point lower than water, steam is generated under reduced pressure and may be compressed. As applied to a continuous apparatus for distilling crude mineral oil, the oil is passed by a pipe 1, through a dephlegmator *D*, a water separator *E* and a preheater *F* to a column *A* in which petrol vapors are driven off and condensed in the dephlegmator *D*. The oil passes from the column *A* through a pipe 9, heater *I* and pipe 14 to a column *B*. The oil passes from the base of the column to a boiler *C*, the residues from which pass to the preheater *F*. Vapors pass from the column *B* by three pipes 11, 12, 13. The heavy vapors from pipe 13 are condensed in the heater *I*, those from the pipe 12 pass to a steam-generator *K*, which is kept, for example, under a pressure of 6 atmospheres, so that steam is generated at about 189 deg. C. by vapors at a temperature slightly above

this—namely, about 163 to 165 deg. C. The light vapors from the pipe 11 pass to a second steam generator *L*. The steam from the generator *K* may be used in the heater *G*, the condensed water from which is returned to the generator *K* by a pump *P*. Residual steam and the steam from the generator *L* pass to a cylinder *M*, from which the steam may pass for the production of motive power, or may be compressed by a device *T* and used for heating purposes. The various oils condensed pass through a refrigerator *J* to the test glasses *H*. In non-continuous apparatus the vapors from a still are passed through a steam generator on their way to a condenser. (Br. Pat. 154,558, not yet accepted; L. GRANGER, C. MARILLER and SOC. ANON. D'EXPLOITATION DE PROCÉDÉS ÉVAPORATOIRES, Paris. Feb. 2, 1921.)

Phenol-Aldehyde Condensation Products.—The condensation of phenols with aldehydes, such as formaldehyde solution or paraformaldehyde, is effected or completed in the presence of the following condensing agents which react with the water present or produced—namely, metal carbides, nitrides, cyanamides, silicides or phosphides. Where such bodies are used only for completion of the process, the initial stage of the condensation may be carried out with aqueous formaldehyde by the usual methods, the layer of condensation product separated from the aqueous layer and then treated with the specified condensing agents. According to examples there are employed: Phenol, paraformaldehyde and calcium carbide; cresol, paraformaldehyde and calcium cyanamide or aluminum nitride; an example is also given in which cresol is condensed with aqueous formaldehyde in the presence of ammonium chloride, and the separated resin is treated with calcium carbide. The insoluble infusible products finally obtained are water-free and have high insulating properties. The provisional specifications are not confined to the specific condensing agents mentioned above, and refer also to the use of sodamide, metal alcoholates and the compounds of ammonia with zinc or calcium chloride. (Br. Pat. 154,656, VICKERS, LTD., Westminster,

and IOCO RUBBER & WATERPROOFING CO and W. H. NUTTALL, Glasgow. Feb. 2, 1921.)

Alkali Bichromates.—Sodium and potassium chromates are converted into their respective bichromates by the addition of the corresponding acid sulphate. For example, by adding sufficient potassium hydrogen sulphate in the form of a coarse powder to the hot solution of potassium chromate, all the latter is converted into potassium bichromate. After filtering, the solution is concentrated, when potassium sulphate separates. From the mother liquor, after all sulphate has been removed, potassium bichromate is obtained by crystallization. (Br. Pat. 154,810, R. L. DATTA, Calcutta. Feb. 2, 1921.)

Concentrating Ores.—In a froth flotation process for concentrating ores, particularly oxidized ores of copper, lead, etc., the ore is suspended in water to which is added a minute proportion of oleic acid or its near homologues, and a minute proportion of sodium silicate, with or without sodium carbonate, caustic soda or other alkali, and agitation and aëration are effected as usual. The oleic acid or the like may be added at the stage of wet-grinding as described in specification 18,937 (1913). The concentrate may be re-treated with the addition of more sodium silicate but without further addition of oleic acid, etc. The apparatus used may be such as that described in specification 18,937 (1913). (Br. Pat. 154,870, not yet accepted; MINERALS SEPARATION, LTD., London. Feb. 2, 1921.)

Strengthening Organic Tissues and Substances.—The tensile strength of organic tissues and substances such as leather, horsehair, catgut, flax, cotton, etc., is increased by impregnating with "diatomic phenols such as guaiacol, veratrol, etc., in alcoholic or other solutions of varying concentrations." The subsequent evaporation or sublimation of the phenols may be prevented by treating the impregnated material with sodium or potassium formate, carbonate or oxalate, which reacts with the guaiacol or other substance or the surface of the material forming insoluble compounds. (Br. Pat. 154,881, not yet accepted; C. HENRY, Paris. Feb. 2, 1921.)

Alkali and Alkaline Earth Cyanides and Cyanamides.—In the fixation of nitrogen as cyanides or cyanamides of alkali or alkaline earth metals by the reaction of nitrogen on mixtures of alkali or alkaline earth metal compounds and carbon, the materials, which may be briquetted, are introduced into the furnace in a dry condition, that is, containing not more than 2.5 per cent of water so as to be of sufficient electrical conductivity to avoid the production of arcs. When a shaft furnace is employed, the dry condition of the charge prevents the blocking of the furnace by the formation of lumps. (Br. Pat. 154,896, not yet accepted; C. T. THOSSELL and H. L. R. LUNDEN, Gothenburg, Sweden. Feb. 2, 1921.)

Treatment of Waste Micanite.—Scrap micanite and similar insulating materials are treated as follows for the recovery of the resins and the mica. The scrap micanite is autoclaved with a dilute aqueous solution of ammonia or other alkali, or with a solution of a salt having an alkaline reaction such as borax, and the live steam is admitted at a pressure of 4 to 6 atmospheres for fifteen to thirty minutes. Under this treatment the varnish is softened, and owing to the tendency of the mica to regain its original form before compression the solvent penetrates between the layers and dissolves the varnish. Alternatively the micanite is autoclaved with water instead of the alkali and the varnish dissolved after this treatment by immersing the mica while still hot in a cold alkaline solution. The strained alkaline solution, preferably after concentration, is then neutralized and heated to precipitate the resins. (Br. Pat. 155,318; H. C. S. DE WHALLEY and MICANITE & INSULATORS CO., London. Feb. 16, 1921.)

Aromatic Amines.—The reduction of aromatic nitro, nitroso or azo compounds is effected by means of cast-iron borings or turnings and an aqueous solution of a metal chloride, such as sodium, calcium or ferrous chloride; the treatment of nitrobenzene and of nitrophenol benzylethers or their homologues or halogen derivatives is excluded. (Br. Pat. 155,319; T. S. MOORE, Egham Hill, Surrey. Feb. 16, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Study of Non-Metallic Structural Materials Proposed

Congress has been asked by the Bureau of Mines for a supplemental appropriation of \$47,000 to undertake a study of the structural clay products and other non-metallic building materials. The proposed work is to be under the immediate direction of Dr. R. B. Moore, chief chemist of the bureau. The appropriation is asked as a result of the many requests which have come to the bureau for information as to the technological phases of structural materials.

KILN DESIGN AND FUEL ECONOMY

An important factor contributing to the market increase in costs of brick and tile is the added expense of fuel. Coal is selling at the mines for three times its pre-war price. The cost of laying it down at clay products plants has doubled, largely due to the increase in freight rates. A large percentage of brick and tile plants is located unfavorably with respect to fuel supplies. Most kilns now in use are very wasteful of fuel. With fuel affecting the price so importantly, the makers of clay products are clamoring for information as to how kiln design may be improved so as to use the minimum amount of coal.

The Bureau of Mines is in a particularly good position to furnish information along the lines set out in the foregoing, as it conducted extensive specialized research work in fuel economy during the war and always has given the general problem much attention.

Breakage of finished brick and tile results in very considerable losses. It is believed that systematic experimentation will develop that this breakage can be reduced materially.

MANUFACTURE OF BRICK

There are other economies and efficiencies which it is believed the clay industries can adopt. Generally speaking very few important improvements have been made in the manufacture of brick during the past twenty years, it is declared. It is believed that machinery can be improved and that more efficient methods of handling raw materials and finished commodities can be introduced. The matter of a more intelligent selection of raw materials also opens a wide field for research that is likely to be helpful to these industries.

Brick production this year is going forward at one-third the rate of production maintained in 1906. Prices are said to be four to five times higher than those obtained in 1913. Even with the limited amount of construction done in 1919, the country produced \$184,000,000 worth of clay structural products. In view of those facts, it is held that any improvement in the practices of the industry will have a direct effect in reducing prices of the finished materials—the greatest obstacle impeding housing construction on a scale commensurate with the country's needs.

Since brick and tile are manufactured for the most part by small operators, the amount of research and experimentation has been relatively much smaller than in the case of industries where there are a limited number of large producers.

CEMENT, SLATE AND FELDSPAR

Cement, slate and feldspar studies also will be undertaken if Congress will make the appropriation. It is proposed to study the extension to building construction the use of "sand cement," which has been employed so successfully in Reclamation Service projects. Improvement is believed possible in the proportioning of materials used in many cements and in the methods used in mixing and grinding.

In such limited investigations of the slate industry as

already have been undertaken by the Bureau of Mines, it has been established that the solution of that industry's greatest problem is the finding of uses for waste slate. It has been found that it can be ground and made into a very durable roofing material. It is believed that means can be found for utilizing much of the waste material. The result would be the placing of the industry on a more substantial footing and make possible price reduction.

With the growth of the pottery industry, there is an increasing demand for feldspar of high quality and uniform grade. A thorough survey of the industry is declared to be imperative. The plan is to determine the probable reserves of high-grade feldspar in the United States. Methods of quarrying and grading would be studied with the idea of suggesting improvements. It also is proposed to establish standard grades of this material. It is suggested that the material suitable for electrical porcelain and vitrified whiteware could be graded differently than that suitable for the lower grades of pottery.

New Chemistry Building for Columbia University

Initial steps have been taken by the trustees of Columbia University to carry out the big building program outlined by President Nicholas Murray Butler two years ago. Preparation of plans for two new buildings, one to be devoted to the department of chemistry and the other for use as a faculty club, has been authorized.

The new chemistry building will be thoroughly modern in construction and equipment and will be built on Broadway immediately north of Havemeyer Hall. It will contain provision for instruction and research in chemistry and chemical engineering and allied subjects. The faculty club building, the cost of which two years ago President Butler estimated at \$300,000, will be located at Morningside Drive and 117th St., adjoining the president's house. The building program indicated by President Butler at that time called for an expenditure of several million dollars.

It is proposed to erect the chemistry building and the faculty club building with funds recently received by the university in unrestricted legacies.

In a statement prepared for the University Council Dr. Butler says that some of the more urgent physical demands of the university should be satisfied. The weakest point in the university at the present moment is the lack of sufficient equipment for instruction and research, particularly in those fields where extensive laboratories are required.

"Probably no one will dispute the statement that the central science just now," added Dr. Butler, "the one that is likely to remain the central science for some time to come, is that many-sided body of knowledge called chemistry."

Quebec Pulp-Wood Business at Standstill

The pulp-wood business in Quebec, like the lumber trade, is practically at a standstill, reports Vice-Consul Arthur B. Giroux, at Quebec. Quebec dealers interviewed say they cannot account for the lack of demand from the United States except that American mills are still stocked with wood and paper products. The dealers, however, are waiting for readjustment, and state that they can and will wait until conditions are better and the prices assert an upward trend.

Quebec farmers, who for some years past have cut pulp wood from their farm woodlands, have stopped cutting. The tendency is to wait for a settlement of conditions, and it was stated that no more pulp wood would be cut until the prices are increased.

Plan to Extend ad Interim Dye Control

After having heard testimony to the effect that German dyes would be dumped upon the American market if the authority of the War Trade Board were not extended, Senator Knox introduced the following amendment to his peace resolution:

Provided further, that on and after the day following the passage of this act, for the period of six months, no sodium nitrite, dyes, dyestuffs, including crudes, intermediates and other products derived directly or indirectly from coal tar, and no finished or partly finished products, mixtures and compounds of coal-tar products, and no other synthetic organic drugs, or synthetic organic chemicals, shall be admitted to entry or delivered from customs custody in the United States or in any of its possessions unless the Secretary of the Treasury shall determine that such article or a satisfactory substitute therefor is not obtainable in the United States or in any of its possessions on reasonable terms as to quality, price and delivery, and that such article in the quantity to be admitted is required for consumption within six months by an actual consumer in the United States or in any of its possessions, and the Secretary of the Treasury may make all rules and regulations necessary and proper for the accomplishment of the purposes of this proviso. And upon the day following the approval of this act the War Trade Board Section of the Department of State shall cease to exist; all clerks and employees of the said War Trade Board Section shall be transferred to and become clerks and employees of the Treasury Department; all books, documents and other records of the said War Trade Board Section shall become books, documents and records of the Treasury Department; all individual licenses issued by the War Trade Board Section prior to the passage of this act shall remain in effect and the importations under such licenses shall be permitted; all unexpended funds and appropriations for the use and maintenance of the said War Trade Board Section shall become funds and appropriations available to be expended by the Secretary of the Treasury in the exercise of the power and authority conferred upon him by this proviso; and for carrying out of the purposes of this proviso during the fiscal year ending June 30, 1922, the sum of \$50,000 is hereby appropriated.

The anti-dumping bill, which was made a part of the emergency tariff legislation, does not protect the chemical industry, since it is so distinct from other classes of production whose protection is sought by that legislation.

Deputation of Engineers Will Present the John Fritz Medal to Sir Robert Hadfield

To express the obligation which the world owes to the engineers of Great Britain for the part they played in winning the war, the organized engineers of America will send a mission to London this summer. This mission, consisting of nationally known engineers and representing the so-called Founder Societies, will make the award of the John Fritz Medal to Sir Robert Hadfield at the opening meeting of the British Institution of Civil Engineers on June 29.

The inability of Sir Robert to come to the United States to receive the medal moved the trustees of the board to make the ceremony of presentation in England the occasion for an international expression of appreciation by the engineers of the United States to the engineers of Great Britain.

The deputation to England will consist of a representative of each of the four Founder Societies represented on the John Fritz Medal Board of Award as follows:

Charles T. Main of Boston, the American Society of Civil Engineers; Colonel Arthur S. Dwight of New York, the American Institute of Mining and Metallurgical Engineers; Ambrose Swasey of Cleveland, the John Fritz Medal Board of Award and the American Society of Mechanical Engineers; Dr. F. B. Jewett of New York, the American Institute of Electrical Engineers. Dr. Ira N. Hollis, president of Worcester Polytechnic Institute and past president of the American Society of Mechanical Engineers, will accompany the deputation and bear the message from the American engineers.

The John Fritz Medal is a gold medal presented for achievement in applied science as a memorial to the engineer whose name it bears. Previous recipients of the medal have been John Fritz, Lord Kelvin, George Westinghouse, Alexander Graham Bell, Thomas Alva Edison, Charles Talbot Porter, Alfred Nobel, Sir William Henry White, Robert Woolston Hunt, John Edson Sweet, James Douglas, Elihu Thomson and Henry Marion Howe. The medal is awarded to Sir Robert Hadfield this year because of his invention of manganese steel.

The medal was established by the professional associates and friends of John Fritz of Bethlehem, Pa., on Aug. 21, 1902, his eightieth birthday, to perpetuate the memory of his achievements in industrial progress. There are no restrictions on account of nationality or sex. The trust funds supporting the medal are held and administered by a board of sixteen directors, consisting of four from each of the four national engineering societies represented on the mission to England.

The admiration felt by the American engineer for his British fellow-worker is expressed by Calvin W. Rice, secretary of the American Society of Mechanical Engineers, in a communication to Dr. J. H. T. Tudsbery, secretary of the Institution of Civil Engineers, London, in response to cabled greetings:

"There is a very deep sense of gratitude and obligation on the part of the engineering societies of the United States for the part played by the engineers of Great Britain in the war, and it has been a great deprivation to us that we could not have sooner expressed this in an adequate manner. It is the desire on the part of the engineers of the United States that the presentation be as simple as possible and yet be sincere."

In response to this communication the British Institution of Civil Engineers cabled that it would "welcome and appreciate very highly greetings from the engineers of America at the opening meeting on June 29," and that they "found the occasion very suitable for the presentation of the John Fritz Medal to Sir Robert Hadfield."

License Required for Importation of Sodium Nitrite From Enemy Territory

The War Trade Board Section of the Department of State announces that General Import License PBF37 has been corrected to include importations of sodium nitrite among the materials, products and commodities importations of which are excepted from its provisions. Specific individual licenses are now required for: (a) sodium nitrite, (b) synthetic organic drugs, (c) synthetic organic chemicals, (d) dyes and dyestuffs, including crudes and intermediates, (e) all products (whether embraced in the above or not) derived directly or indirectly from coal tar, including crude, intermediate and finished or partly finished products and mixtures and compounds of coal-tar products.

The action in regard to sodium nitrite was taken after conferences between F. S. Dickson, acting chairman of the board, other Government officials, representatives of the American Nitrogen Products Co. of Seattle and representatives of American dye manufacturers. Importation of Norwegian sodium nitrite will not be affected by this ruling.

In addition, a revised and simplified form of instructions for filing applications for licenses has been issued.

Fellowships in Metallurgy

Several fellowships are to be awarded at the University of Utah, Salt Lake City, each having an annual value of \$720, open to college graduates with good training in chemistry and metallurgy. The work will be in the department of metallurgical research, University of Utah, which is maintained in connection with the Utah Station of the United States Bureau of Mines. The problems to be studied are in general ore dressing, or special problems bearing on the flotation of ore, application of volatilization process to gold, silver, lead or copper ores, the hydrometallurgy of zinc, or investigations on oil shale. Full details may be had from Joseph F. Merrill, director.

Hoover Requests Additional Funds

To make possible additional assistance to the export industries, the Secretary of Commerce has requested supplemental appropriations aggregating \$618,728.34. Of that sum \$250,000 is to be used by twelve new divisions which it is proposed to establish in the Bureau of Foreign and Domestic Commerce. It is planned to have a separate division to be of direct assistance to each of the following industries: chemicals (including dyestuffs), cotton and cotton goods, paper and paper products, leather and leather products, machinery, electrical goods, automobile and accessories, lumber and lumber products, metal products, vegetable oils, hardware, jewelry, and silverware. The entire time of two specialists would be devoted to each of the industries mentioned, if Congress should approve Secretary Hoover's plan. In addition each division could make specialized use of the mass of foreign trade information which is constantly reaching the bureau and would keep up to date the market investigations which the bureau has been conducting during the last five years.

An additional \$100,000 is requested by Secretary Hoover for an investigation by the Bureau of Standards into industrial wastes and the development of commercial uses for byproducts.

Another \$100,000 would be allotted to the Bureau of Standards for an extension of its work in the matter of standardization of equipment. Mr. Hoover holds that it is of first importance to those engaged in foreign commerce to establish manufacturing and commercial standards of machinery, equipment and devices, including the elimination of unnecessary forms, varieties and qualities. He points out that the Department of Commerce is in a position to co-operate with both manufacturers and users in bringing about voluntary standards of this kind.

It is proposed further by Mr. Hoover to allot \$50,000 to the Bureau of Standards for the standardization of housing construction, the development and dissemination of knowledge concerning building materials and their uses and the establishment of building codes. Since building codes are of a highly scientific character, Mr. Hoover points out that extensive investigation is necessary so that they may be formulated with due regard to economy, durability, safety and the materials locally obtainable.

The remainder of the fund requested is allotted largely to salary increases throughout the department. Mr. Hoover has stated frequently since taking charge of the department that inadequate salaries form the basis of many of the department's difficulties.

Philadelphia Section Meeting, A.C.S.

A varied program was presented at the regular monthly meeting of the Philadelphia Section of the American Chemical Society, held at the Engineers' Club on Thursday evening, April 21. The dinner speaker was Richard Spillane, editor of the Business Section of the *Public Ledger*. He presented a very interesting and comprehensive survey of business conditions in Europe and of our foreign trade possibilities throughout the world. He emphasized particularly the splendid opportunity that China offers us in her enormous undeveloped mineral and agricultural resources. South America, with its untapped reservoirs of oil, also offers excellent possibilities. In conclusion, Mr. Spillane made a special appeal to chemists "to meet our friends the public by talking and writing in plain, simple English, so that ordinary people can understand it. Chemistry is enveloped in too much of a fog. Let there be the sun of understanding."

WORK OF BUREAU OF STANDARDS

At the formal meeting of the section, W. C. Wagner of the Philadelphia Electric Company spoke on "Recent Developments in the Work of the Bureau of Standards." His talk was illustrated with a large number of slides, many of which were prepared and released expressly for this meeting. Balances were shown ranging from a small assay balance accurate to 0.001 mg. up to a large railroad machine for calibrating track scales. In steel-testing work

moving pictures of the gages are taken and the instantaneous readings thus obtained are proving very valuable.

In the electrical work, standards of resistance are in use which are accurate to one millionth of an ohm, and potential differences can be measured with an accuracy of 0.00001 volt. In calibrating electrical instruments a magnifying camera is used for projecting the face of the instrument, and thus, by avoiding parallax, an accurate reading is easily obtained. A magnetic device has been developed for determining the integrity of steel. This was especially applicable during the war in detecting internal flaws in steel for rifle barrels. The relative hardness of different steels can also be determined magnetically. The speaker predicted that one of the important developments along this line in the near future would be the use of this device by the railroad companies for detecting flaws in rails. In studying the electrolytic corrosion of pipe, it has been found that if the moisture content of the earth rises, through faulty drainage, above 18 to 20 per cent, the rate of corrosion increases very rapidly.

In the aeronautical work at the Bureau of Standards, special attention has been paid to the testing of airplane motors. A "stethoscope of the gas engine" has been developed by which a great deal of valuable information has been obtained on the performance of different types of motors. For example, it has been possible to determine the relation between the viscosity of the lubricating oil and the electric power required to start the motor. Pictures were shown of the "vacuum chamber" where Liberty motors were tested under the same conditions as would be encountered in actual service.

Several other interesting phases of the work were mentioned. In the radio work, antennae were developed for use on airplanes, so that, with the instruments in the landing field sounding a certain keynote, a safe landing could be made in total darkness. In the radium section, flaws in steel plates are detected by means of radium photographs. The photographic section has developed improved plates for taking airplane pictures in smoky or foggy weather. Mr. Wagner concluded by praising the Bureau of Standards for its excellent work on optical glass.

REFRACTOMETRY

The last speaker on the program was Warren P. Valentine, who gave an illustrated talk on "Refractometry." He discussed the principles of refraction and the different types of instruments that are based on the principle of total reflection. There is a definite relation between the percentage of solid in a solution and the refractive index. The refractometer can therefore be used for the analysis of almost any solution that is clear enough to transmit light. It can also be used to determine specific gravity, and when used for this purpose special scales can be set on the instrument. Mr. Valentine has manufactured the first American Abbe-type refractometer, and the Bureau of Standards has certified that the accuracy of his instrument is greater than that of any refractometer heretofore imported from Europe.

Oil-Fired Converters

Three Scottish firms have installed the Stock oil-fired converter for the manufacture of steel castings, according to *The Iron Monger* for March 26, 1921. The Stock is a small side-blow converter in which the cold pig iron and scrap can be melted before deoxidation by means of oil fuel, which is introduced at a pressure of about 40 lb. per sq.in., and for the combustion of which a suitable supply of air is admitted. Melting occupies from forty minutes to an hour, and when this is completed the oil is cut off and the converter is rotated into a slanting position. A blast of heated air is then introduced from the side of the converter at such a level that it produces agitation only at the surface of the metal. Blowing usually occupies about a quarter of an hour. The main advantages of this method are that no impurities are taken up by the pig iron during melting, and that the high temperature obtained results in a very fluid metal which makes the process very suitable for the production of castings.

Inspection Trips at A.S.M.E. Spring Meeting, Chicago

Industrial Chicago has many things to show the mechanical engineer, and is going to throw them open to inspection by those attending the spring meeting of the American Society of Mechanical Engineers, May 23 to 26. The places which offer to entertain guests in this way are too numerous to be seen by all within the four days of the meeting, so several are scheduled for each day, so arranged, as far as possible, that the individual may suit his taste by selection daily without feeling that he is missing something he would like to see.

Tuesday: International Harvester Co., McCormick and Deering plants; Sears, Roebuck & Co., wall paper manufacture, handling and shipping merchandise; Mandel Bros., package handling, coal and ash handling, connection to sub-street tunnel system; Western Electric Co., manufacture of telephone apparatus and cable for the bell telephone system.

Wednesday: Illinois Steel Co., South Works, South Chicago, plate mill, rail mill, bessemer converters and general steel mill equipment; Commonwealth Edison Co., modern turbine central station at Fisk St.; Pennsylvania Lines terminal, freight handling plant, in connection with which there may be visited the neighboring warehouse of Marshall Field & Co. and the U. S. Terminal Building; Crane Co., manufacture of valves and fittings in cast iron, malleable iron, steel and brass, the fabrication of pipe work.

Thursday: Chicago Mill & Lumber Co., 120-in. paper machine, manufacture of fiber, corrugated board and paper boxes; Clemetsen Co., manufacture of veneers and "Clemco" office desks; Pullman Co., Pullman cars, passenger coaches and freight cars; Underwriters Laboratories, testing of appliances and devices for fire prevention; Yellow Cab Manufacturing Co., where the ubiquitous cabs come from.

Friday: Milwaukee Railway & Light Co.'s Lakeside plant, trip by rail to Milwaukee, boilers fired with powdered coal; Joseph T. Ryerson & Sons Co., warehouses of about 1,000,000 sq.ft. devoted to machinery and steel products.

Chicago Chemists Discuss Photochemistry and Elect Officers

On Friday evening, April 22, the Chicago section, A.C.S., met in Steven's Restaurant, having as guest of the evening Prof. J. H. Mathews of the University of Wisconsin. Members of the Chicago Microscopical Society and of the Camera Club also attended. In the absence of Prof. W. Lee Lewis, Dr. Ethel M. Terry presided.

The speaker's topic was Photochemistry. He pointed out that the use of chlorophyll in vegetation as a photochemical sensitizing agent does not preclude the possibility of finding other chemical agents which may be much superior. Furthermore, the sun is not a satisfactory source of light for photochemical research, because of its inconsistency of energy intensity. The best approach so far to an ideal is a mercury vapor lamp. The spectrum lines in this lamp can be increased by the addition of various other metals, forming amalgams. Of interest is the fact that because the eye is sensitive to only a portion of the spectrum, benzene and acetone are looked upon as colorless, though they both yield definite lines in the spectrum.

In reference to the bactericidal action of rays, Prof. Mathews' belief is that the ultra-violet ray will never be of commercial value for the sterilization of milk. He also spoke of a "new" method of pasteurization recently announced in Detroit whereby milk is treated by the electric current—but, as he cleverly pointed out, the heat generated is equal to that employed in the usual pasteurization plants!

Preceding the talk, the annual balloting for officers occurred. W. Lee Lewis was re-elected chairman; H. G. Walker was elected first vice-chairman, O. C. Stanger second vice-chairman, S. L. Redman secretary, Otto Berndt treasurer, Paul Van Cleef editor, R. E. Doolittle, P. N. Leech, H. N. McCoy, C. S. Miner, L. V. Redman, W. R. Smith, A. M. Taylor, L. M. Tolman and G. L. Wendt councilors. The Willard Gibbs jurors chosen were W. D. Harkins, Julius Stieglitz, E. W. Washburn and David Wesson.

Molybdenum Steel

"Molybdenum Steel" was the subject at the April meeting of the American Society for Steel Treating, Washington Section, on April 22. Dr. George W. Sargent of the Molybdenum Corporation of America discussed the occurrence and characteristics of the richer ores of molybdenum now being mined in this country. By comparisons with other metals and assisted by lantern slides, he brought out some of the history of the uses and the present practice which has led to the application of molybdenum in various carbon and alloy steels. He emphasized particularly the possibility of substitution of molybdenum for carbon in some of the heavier rails now used and in some structural metal.

Martin H. Schmid, speaking at the same meeting, brought out some of his experiences as the metallurgist of the United Alloy Steel Corporation. He emphasized particularly the substitution of molybdenum in smaller percentages than formerly deemed the best practice. The possibilities of molybdenum in chromium, nickel or other alloy steels were also pointed out, with particular attention to the formation of double carbides and the beneficial effect due to diffusion in the ferrite in chrome-molybdenum alloys. Some of the considerations guiding a customer in his selections of an alloy steel were stated by Mr. Schmid as follows:

(1) Compliance with specifications. (2) Availability of raw materials. (3) Freedom from patent litigation. (4) Uniformity of commercial product. (5) Responsiveness to thermal manipulation with reasonably wide temperature ranges. (6) Satisfactory mechanical performance and machinability.

The several methods of adding molybdenum to steel were considered and the advantages of each procedure pointed out. The standard practice suggested by Mr. Schmid is the addition to the charge in the furnace while melting down, as this is claimed to give better diffusion and superior uniformity of finished product. Mr. Schmid also discussed the possibilities of molybdenum steels from the standpoint of the shop and the rolling mill. This metal apparently rolls well without special precautions and permits of wide temperature ranges during working, either rolling or forging. The scale is loose and is easily eliminated, as it flakes freely from the metal and does not show a tendency to roll into the surface. As a result cleaner forgings which require a minimum of expense for cleaning are generally obtainable. The wide range of quenching temperatures which can be used is also cited as an advantage in contrast with certain other steels, the preparation of which requires very close temperature control.

The Washington Section at its next meeting, May 18, will have two speakers dealing with the heat-treatment of ordnance steel and heavy forgings. P. E. McKinney of the Washington Navy Yard, and Lawford H. Fry, production manager of the Standard Steel Works, will be the speakers. At the June meeting, Dr. Enrique Touceda will speak on malleable iron.

Dyes Discussed at Meeting of Connecticut Valley Section, T.A.P.P.I.

The April meeting of the Connecticut Valley Section of the Technical Association of the Pulp and Paper Industry, held in Holyoke April 20 was featured by an address on "Dye Manufacture" by W. F. Van Riper of E. I. du Pont de Nemours & Co. Mr. Van Riper exhibited motion pictures showing various steps in the manufacture of dyes.

In his talk he outlined the growth of the American dye industry during and since the war and stressed the importance of dyestuff manufacture to a nation not only because of its peculiar situation as a key industry on which many other products are dependent but also because of its potential value as a source of military explosives in case of war.

Of particular interest to the paper makers gathered to hear him was his description of factory standardization of colors, for a paper maker must know that one lot of color will be like another in tone and shade, else there is trouble.

After the address many questions were asked the speaker and some interesting experiences with colors brought out.

Personal

HOWARD C. ARNOLD, formerly chief chemist and plant manager of B. F. Drakenfeld & Co., manufacturer of ceramic colors, 50 Murray St., New York, has joined the staff of Arthur D. Little, Inc., Cambridge, Mass.

H. FOSTER BAIN has been nominated by the President to continue his present incumbency as Director of the U. S. Bureau of Mines.

Dr. OSKAR BANDISCH, formerly Privat Docent in the University of Zurich and student under Profs. Werner and Bamberger, has accepted a position as research associate in biochemistry in the Graduate School of Yale University. Dr. Bandisch will affiliate with the department of chemistry and co-operate with Prof. T. B. Johnson in the promotion of biochemical research.

EINAR CHRISTENSEN has recently been placed in charge of the chemical developments of the Cinder Products Corporation, Rochester, N. Y., a new corporation engaged in the manufacture of building material from cinders.

HERBERT G. CLOPPER, formerly with the New Jersey Zinc Co. and more recently vice-president of the Eagle-Picher Lead Co., has become president and treasurer of the Multiple Storage Battery Co., Jamaica, L. I.

DALTON M. GOETSCHUS, who was engaged by B. F. Drakenfeld & Co., Inc., to take charge of its plant at Washington, Pa., will continue his research and experimental work on radium extraction for the Standard Chemical Co. Howard B. Goetschius has taken over the management of the Drakenfeld plant.

Prof. F. GOWLAND HOPKINS of Cambridge University, England, addressed the graduate students of Yale University on the afternoon of April 4, 1921.

M. E. KESSLER has resigned from the chemical staff of the Niagara Alkali Co., and is now associated with the Waste Products Co., Niagara Falls, N. Y.

Dr. PAUL E. KLOPSTEG, who has been connected with the sales and advertising department of Leeds & Northrup for several years, has recently accepted a position with the Central Scientific Co. of Chicago, as manager of development and manufacturing.

H. M. MINER has been appointed New York representative of the Cleveland Cliffs Iron Co., Cleveland, Ohio, producer of methanol and wood chemicals.

O. E. RUHOFF, formerly chemical engineer for the French Battery & Carbon Co. of Madison, Wis., has severed his connection with this company in order to associate himself with the Industrial Research Laboratories of Chicago.

DAVID T. SCHULTZ has left his position as chemist in charge of the analytical laboratories of the Atlantic Refining Co. to become chief chemist of the New England Oil Refining Co., Fall River, Mass.

ARTHUR C. TRASK has resigned as vice-president of the Marden, Orth & Hastings Co., Inc., to become vice-president of the Falk Co., Pittsburgh, Pa., which company plans to equip a plant at Carnegie, Pa., for the refining of menhaden fish oil and for the sulphonating and processing of oils.

Obituary

CHARLES S. HAWES, in charge of the Bureau of Research and Statistics of the War Trade Board Section of the Department of State, died suddenly on Friday, April 22, in Chicago, Ill., where he was on a special investigation for the department. Death was due apparently to apoplexy and occurred at the home of Philip O. Palmer. He is survived by his wife, Mrs. Frances Wilson Hawes.

New Jersey Ceramic Exposition

The Newark, N. J., Society of Ceramic Arts held its annual exhibition at the Free Public Library during the week of April 18-23. The display was arranged on the fourth floor in the museum department and presented many interesting exhibits. Luster ware was rather the predominating feature, and there were fewer examples of delicate china and porcelain than in previous years. The exhibit showed many attractive specimens of pottery of the more substantial varieties.

Air Reduction Co. Acquires National Carbide Corp.

On May 1 the Air Reduction Co., New York, manufacturer of oxy-acetylene cutting and welding apparatus, took over the control of the National Carbide Corporation of Virginia, and in the future will direct the operating policy and sales of the organization. The acquired company's plant at Ivanhoe, Va., will be continued in operation for the production of carbide. This location has proved decidedly advantageous with regard to low costs for water power, coke and lime, as used at the works. With this acquisition, the purchasing company is in direct control of all materials and equipment entering into the production of its specialties.

Current Market Reports

Chemical and Allied Industrial Markets

NEW YORK, May 2, 1921.

Weakness is still evident in the chemical market and inquiries have not changed in character to any unusual degree during the past week. The turn in the stock market has been taken as a hopeful sign by factors in heavy chemicals and while no actual increase in buying has been noted there seems to be a general feeling of optimism throughout the trade. Conservatism is the keynote among buyers. There was a fairly active demand for light and dense *soda ash* in carload lots and producers have placed considerable business because the spot market has been practically sold out and second hands have not been in a favorable position to force keen competition with the manufacturers. In some quarters, however, there was some shading on contracts for the light *soda ash* and business has been booked at \$1.62½ per 100 lb., basis 48 per cent, f.o.b. works, in single bags, instead of \$1.72½. Competition of English producers of ash is attracting attention in the American market. There has been a large tonnage sold at \$1.90 per 100 lb. laid down in N. Y. Contracts on *caustic soda* have been offered at 3¼c. per lb., basis 60 per cent, f.o.b. works for prompt and future shipments, with sales recorded a shade under this quotation. The demand for caustic has not been as active as that for ash. At any rate, spot prices have been generally maintained. First-hand sales of caustic have been made at 3¾c. per lb., basis 60 per cent, f.o.b. works. Spot lots of *bichromate of soda* have brought 7¼c. per lb. Buyers have not been eager to pay this price, but holders of resale goods have remained firm in their views. *Bleaching powder* has developed an easier tendency and prominent sellers have sold at 2¼c. per lb. in large drums. There was moderate trading at this figure and the inquiry has been of fair dimensions all week. There has been a strong evidence of German competition reflected in *caustic potash*. This material is offered so far below the American figures that competition is practically out of the question for the present. Sellers of the 88-92 per cent caustic potash stated that offers for shipment have been heard as low as 4¼c. per lb. Resale lots on spot have sold down to 5¼c. per lb. German *chlorate of potash* has been offered for shipment at 6c. per lb. These disturbing influences are sufficient to cause a cautious attitude among buyers. In the face of all this cut-throat competition the need of a protective tariff is readily seen.

unless American producers accept the inevitable and close their plants. It seems that this is the desire of German producers who are bent on controlling the chemical market. There is no doubt that if the American manufacturer were abolished no such prices as the present would be named. The outlook for prices is very uncertain and will remain so until the new tariff schedule becomes effective. Many authorities in the chemical market are of the opinion that we will not experience anything approaching a general revival of business until next fall.

CHEMICALS

Prices in *alum* have remained practically unchanged on routine trading. *Ammonia alum* prices are based on 4@4½c. per lb. for the lump. *Potash alum* is quoted on the basis of 5@5½c. per lb. *Ammonia chrome alum* is quoted at 13@14c. per lb. Price cutting in *bleaching powder* is widespread among holders of any sizable stocks and quotations of \$2.40@\$2.50 per 100 lb. is subject to considerable shading. Makers are holding for \$2.75 at the works. Rumors of prices as low as \$2.10 f.o.b. works could not be confirmed, but from the weak tone of the market these prices are not considered out of line. Prices on *copper sulphate* are quoted at 5½@6c. per lb., according to makers and quantity. The market has been somewhat weaker, but first hands are not inclined to force business by any price cutting. Scattered transactions in resale *bichromate of potash* were reported at 11½c. per lb. on spot. Dealers quoted the market at 11½@12c. Demand has not shown much activity during the week and the situation remained rather quiet. A further reduction on *permanganate of potash* brought the price down to 32@35c. per lb. Limited supplies of *yellow prussiate of potash* are holding the spot market steady and sellers are not eager to shade 26c. per lb., with some asking up to 27c. for small quantities. The red variety has remained quiet, with sellers quoting from 35@40c. per lb. Prominent sellers of prime *muriate of potash* quoted \$50 per ton, basis 80 per cent, delivered. A fair inquiry is reported for this chemical and transactions of large and small quantities have been recently booked. Leading factors of *chlorate of soda* have reduced the price to 7½c. per lb., f.o.b. works, for prompt shipment. This is the lowest price heard for domestic chlorate since before the war.

Spot prices for light *soda ash* in single bags are heard from \$2@\$2.10 per 100 lb. Resale offerings continued small and the market is reported steady in most quarters. Prominent dealers reported sales of *caustic soda* at 3½c. per lb. ex-store N. Y. The market while quiet looks steady, although it is admitted that odd lots can be purchased below this price. Resale goods f.a.s. steamer were quoted up to \$3.85@\$3.90 per 100 lb. Producers report sales at 3½@3¾c. per lb., basis 60 per cent, f.o.b. works, depending on quantity. The recent advance of *sodium nitrate* by importers has reflected itself by a further strengthening of the resale market. Resale nitrate is quoted at \$2.70@\$2.80 per 100 lb. on a very strong basis against an importers' price of \$3. Prices on *sodium nitrite* are slightly firmer following the restriction of imports by the war trade board. Some holders have been attempting to buy up large stocks so that openly quoted prices are around 5½c. per lb. for spot material. Consumers, in general, have not shown any unusual interest.

COAL-TAR PRODUCTS

The promise of early legislation looking toward a policy following along protective lines has created a better feeling in many quarters of the coal-tar products market and the tone throughout the week has appeared to be of a more hopeful nature. The period of waiting is surely growing shorter and definite action of some sort will put a stop to hesitancy. Fluctuations in intermediates have been narrow as far as producers' figures are concerned and second hands as well are steadier in their views. *Aniline oil* seems to show about the widest range of quotations, while *paranitraniline* and *beta naphthol* show a firmer tendency. The crude market does not show a very uniform volume of trading in the different products and while *naphthalene* and *benzene* are moving in a steadier manner other items are quiet and weak.

Prices on *benzene* quoted by refiners are held steady. Prices are quoted at 27@32c. per gal. for pure benzene in tank cars and drums. The 90 per cent grade is quoted at 25@28c. per gal. on the same basis. Buying in both grades has been of somewhat limited nature. Prices on *naphthalene* are unchanged, with the demand rated fair. Refiners are quoting 8½@9½c. per lb. for the flake and 9½@10½c. for the balls, according to quantity. Resale flake can still be had in some quarters as low as 8c. per lb. Prices on *phenol* are unchanged at recent levels with little demand noted. Quotations in the open market are around 10c. per lb., but stocks are light. Government surplus phenol is still to be had at 12c. per lb., according to quantity.

Resale *aniline oil* can be had around 19c. per lb. in fair quantity, but the quality of material at the low figure is very doubtful. Makers are offering goods as low as 20@28c. per lb., and those naming the lower figures are finding business in fair volume. Consumers are interested only in small lots for immediate requirements and in many cases are preferring to use the inferior grade offered on the spot. Prices for spot *beta naphthol* are very uncertain. Demand has been desultory and few orders of reasonable size have been booked. Resellers are generally quoting around 34c. per lb. with a variation of a few cents either way. Bids at 28c. per lb. have failed to bring out any stocks. Manufacturers are quoting unchanged prices at 40@42c. per lb., but report little interest at this level. Buyers are not inclined to increase holdings beyond immediate requirements. Quotations on *dimethylaniline* are around former levels, with 48c. per lb. quoted by resellers and 55c. quoted by makers. The resale market is subject to shading on firm business.

VEGETABLE OILS

Trading during the week in *castor oil* was inactive, but producers maintained prices on the basis of 10c. per lb. for the U.S.P. No. 1 and 9½c. per lb. for the No. 3 in barrels. Outside lots were available at slight concessions. The spot market for *chinawood oil* closed steady at 10c. per lb., while nearby material could be purchased at 9½c. The coast market for April-May shipment was nominal at 8½c. per lb. A good volume of business in *coconut oil* was placed during the week and prices were somewhat firmer. Some lots of Ceylon type oil sold locally on the basis of 9c. per lb. in drums. One lot of Ceylon type oil was offered during the week for immediate delivery at 9½c. per lb. Cochin quality oil was offered in some quarters on the basis of 10½c. per lb. in barrels, but several holders continued to quote the market at 11c. The production of *corn oil* has been augmented, but offerings are not pressing on the market and prices held on a steady basis. Crude oil locally was nominally unchanged at 7½c. per lb. Refined oil held at 9¼@10c. per lb. for carlots in barrels. *Lagos palm oil* for spot delivery was firmer, the market closing at 7¼@7½c. per lb., according to seller and quantity. On forward business there were offerings of 7c. per lb., with possible shading on firm orders. *Niger oil* was available at less than 6c. per lb., due to the presence of some distressed lots. Business was noted in crude domestic *peanut oil* at 5½c. per lb., buyers' tanks, f.o.b. mill. Some holders of crude oil advanced their prices to 5½c. and in some instances to 6c. per lb., but buyers showed no interest in the higher quotations. English refined *rapeseed oil* was offered on the spot at 91c. per gal. On nearby oil 88c. was possible to be done, with futures available on the basis of 86c. per gal. The market on *soya bean oil* for immediate shipment from the coast held around 5c. per lb. On futures 4½c. represented the nominal quotation, with no buying interest noted on account of the tariff situation.

The Iron and Steel Market

PITTSBURGH, April 29, 1921.

The volume of strictly new buying in steel products has been particularly light in the past week, this being a natural sequence to the price changes that occurred a fortnight and more ago. As the independents advanced their prices at that time buyers had an opportunity to close on quotations then outstanding, and thus a considerable volume of business was rounded up, the buyers having correspondingly less occasion to buy now, while the advance in prices

to such buyers is also a factor. As to the Steel Corporation, whose price change was a reduction, it is receiving specifications against old contracts at a somewhat heavier rate, though on the whole the increase does not seem to be as great as might have been expected.

The quantity of steel consumption has plainly not been affected one way or the other. If the present rate of consumption is equal to the rate of production, it is probably as great a rate as can reasonably be expected under present financial and industrial conditions generally, for the rate is nearly if not quite 40 per cent of capacity. The rate of production during the first nine months of 1920, when the appearance was of heavy consumption and an almost insatiable demand, was approximately 80 per cent of capacity. Comparing general conditions, one would not expect there to be more than one-half as much steel consumption now.

A test of the lightness of steel demand in general is the prominence that is given in trade circles to the steel requirements of the automobile trade, when it is known that the manufacture of automobiles did not consume more than about 5 per cent of the steel production in 1920 and the automobile industry cannot be expected to have nearly as large a production this year as it had last year.

PRICES

Finished steel prices remain quotable as follows: Bars, 2.10c.; shapes, 2.20c.; plates, 2.20c.; hoops, 2.75c.; plain wire, 3c.; wire nails, \$3.25; standard steel pipe, 62½ per cent basing discount; blue annealed sheets, 3.10c.; black sheets, 4c.; galvanized sheets, 5c.; tin plate, \$6.25.

There has been another revision in spike prices. The separate prices on standard spikes, small spikes and boat spikes named in this report a week ago have been withdrawn, and a single base price of 3.40c. has been substituted, this being a reversion to practice before the war, there being extras over the base price for small spikes and the various sizes of boat and barge spikes. The reduction in chain from 6.75c. to 6.35c. by one manufacturer has been followed by a reduction to 6.25c. by others, as a base price, while spreads on sizes ½ in. and smaller were decreased by ¼c.

Some question is already being raised whether the new prices on rolled steel products are being strictly maintained. Cases of apparent shading are usually attributed to "old quotations," though this may be really a sort of subterfuge. Strictly new demand is too light to give the market much of a test, requisitions being chiefly in the form of specifications against old contracts or of releases on orders previously suspended.

PIG IRON AND COKE

The stiffening in the independent market in steel products has not been reflected in any increased strength in pig iron or coke. Thus there is no general stiffening tendency in the iron and steel industry as a whole, the recent operation being simply one of equalization between the Steel Corporation and independent prices for steel products. Foundry iron, formerly quotable at \$25 valley, is being offered at \$24.50 by at least one merchant furnace. Basic iron has again been sold by a steel works interest at \$22.50, the nominal market quotation being \$23, while a quotation of \$22 is understood to have been made to the United Alloy Steel Corporation, which, however, has decided to blow in its furnace and make its iron itself, having the advantage of a byproduct coking plant, for which coal has just been bought.

As to Connellsville coke, which appeared recently to be established at \$3.50, it has sold at \$3.25, and in some quarters there are predictions that the next important sale will be at \$3.

The opening of sales of Lake Superior iron ore for the shipping season of 1921 appears to be no nearer than three months ago. Estimates of the tonnage of ore to be moved this year are still lower, and nearly all the estimated ore will be moved by the producer-consumer class. Early predictions were that there would be a reduction of \$1 a ton from the 1920 schedule, which set Mesabi non-bessemer at \$6.55. That would represent a restoration of the 1919 schedule, but the prospect now is that the reduction will be somewhat greater.

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Alabama

ANNISTON.—The Alabama Mica & Mfg. Co., recently organized, is planning for the erection of a new local plant for the reduction and grinding of mica. A portion of the works will be devoted to the manufacture of mica products. The company has a large tract of mica lands in Randolph Co., which will be developed for raw material supply. Harry H. Wand, Chattanooga, Tenn., is president; A. Albert Tapley, Heflin, Ala., is treasurer.

ALABAMA CITY.—The Birmingham Slag Co., Birmingham, Ala., is considering plans for the erection of a new plant for the manufacture of brick and tile products.

Arkansas

EL DORADO.—The El Dorado Refining Co., Texarkana, Tex., recently organized, is considering the erection of a new plant in the vicinity of El Dorado, with initial capacity of about 5,000 bbl. W. H. Locker, Duluth, Minn., is president.

MENA.—The Cooper Mining & Development Co., Cooper, Tex., is planning for the construction of a manganese ore development plant in the vicinity of Mena. The company has a large tract of property in this section.

EL DORADO.—The Constantin Oil & Refining Co. is reported to be planning for extensions and improvements in its plant, including the installation of a new oil refinery. The work is estimated to cost in excess of \$500,000.

Georgia

ATLANTA.—The Morgan Chemical Co., Ogdensburg, N. Y., is reported to be planning for the construction of a new plant in the vicinity of Atlanta, to cost about \$1,000,000 with machinery. The factory will be devoted to the manufacture of insecticides and other chemical specialties. E. R. Hariman is president.

Indiana

ELKHART.—The American Coating Mills, manufacturer of enameled paper products, is taking bids for the erection of a new 3-story plant at the foot of Division St. It will be known as Plant No. 2, and is estimated to cost about \$300,000 with machinery. James L. Carey, 208 North Laramie Ave., Chicago, Ill., is engineer. C. C. Colburn is president.

Kansas

KANSAS CITY.—The Kansas City Foundry Co., manufacturer of small iron castings, etc., has taken bids for the erection of a new 1-story foundry, 65 x 130 ft., at Water and Walker Sts. E. C. Austin is secretary.

Kentucky

ASHLAND.—The Olive Hill Refractories Co., recently organized, is planning for the construction of a new plant at Olive Hill, Ky., for the manufacture of firebrick and other refractory products. The initial plant will have a capacity of about 30,000 bricks per day. John F. Hager is president and J. William Stewart treasurer.

LOUISVILLE.—The Dixie Belle Refining Co., 105 Inter-Southern Bldg., will soon award the contract for its proposed new oil refinery, estimated to cost about \$500,000 with machinery. The company was organized recently with a capital of \$650,000. G. H. Murphy is president. Carl B. Haun, Blackwell, Okla., is engineer for the project.

Louisiana

NEW ORLEANS.—The J. S. Long Co. is planning for the erection of a new 1-story plant, 100 x 300 ft., to be equipped for the manufacture of soap products.

Massachusetts

AMHERST.—The Massachusetts Agricultural College is having plans prepared for

the construction of a new chemical laboratory at the institution to cost about \$125,000. J. H. Ritchie and G. E. Jonesburg, 15 Ashburton Pl., Boston, Mass., are architects.

Maryland

SILVERHILL.—The Silverhill Sand & Cement Products Co., recently organized, has plans under way for the construction of a new plant for the manufacture of tile, sills, steps and other cement products for structural service. Three 1-story buildings will be erected. John Campbell is president and Frank Bell manager.

Michigan

ST. JOSEPH.—The Fay Foundry Co., manufacturer of iron and brass castings, etc., has awarded a general contract to Max Stock & Sons, Benton Harbor, Mich., for the erection of a 1-story foundry addition to cost about \$25,000. John Fay is president.

Minnesota

ST. PAUL.—The Northwestern Spring Mfg. Co., 3720 University Ave., N. E., has awarded a contract to P. C. Giguere, Minneapolis, for the rebuilding of its spring manufacturing plant in the Columbia Heights section, 2-story, recently destroyed by fire. The new plant will cost about \$100,000. J. W. Hines is head.

Missouri

KANSAS CITY.—The Husted Syndicate Oil Co., 16th St. and Cookson Ave., is planning for the rebuilding of the portion of its oil refinery, destroyed by fire, April 14, with loss of about \$25,000.

Montana

BILLINGS.—The Montana Refining Co. is planning for the construction of a new oil refinery with initial capacity of about 1,000 bbl. The plant is estimated to cost about \$125,000. The company is capitalized at \$500,000. Rudolph Molt is president.

New Jersey

NEW BRUNSWICK.—The Department of Ceramics, Rutgers College, has made a list of machinery and equipment to be installed in the new ceramic school building and will make purchases at an early date. Bids for the new school will be taken at once. It is estimated to cost about \$100,000, and a state appropriation for this amount has been granted. George H. Brown is director of the department.

BAYONNE.—The Standard Oil Co., 26 B'way, New York, has acquired property on East 22d St., between Ave. H and Central Ave., in the vicinity of its oil refinery, Constable Hook, Bayonne, for a consideration said to be about \$270,000. Present buildings on the site will be demolished and the property used for plant extensions.

NEWARK.—The Flexible Cork Co. has leased a portion of the former plant of the Universal Caster & Foundry Co., 124-32 Adams St., for the manufacture of cork specialties. The space totals about 8,000 sq. ft., and the company will take possession about May 1. Equipment will be installed at an early date.

New York

DUNKIRK.—The Thatcher Mfg. Co., manufacturer of glassware, is planning for the erection of modern, fireproof plant to replace its factory destroyed by fire, April 19, with loss of about \$100,000, including machinery. The former works comprised a number of buildings on West Second St.

NEW YORK.—The Mexican Petroleum Co., 120 B'way, has arranged for a bond issue of \$10,000,000, the proceeds to be used for general operations, extensions and improvements in oil refineries, etc. The company is a subsidiary of the Pan-American Petroleum & Transport Co., same address, of which E. L. Doheny is president.

BUFFALO.—The Warner Jewelry Case Co., 682 Michigan Ave., manufacturer of cardboard and fiber containers, etc., is reported to be planning for the immediate establishment of a new local plant to replace its works destroyed by fire, April 19, with loss estimated at about \$125,000.

Ohio

CANTON.—The Whitaker-Greer Fireproofing Co., manufacturer of fireproof building products, has resumed operations at full capacity at its plants at Magnolia and Waynesburg, O., following a shutdown of several months due, in part, to labor troubles.

Ontario

TRENTON.—The Chemical Products Co., Ltd., Toronto, is planning for the construction of a new acid phosphate plant at its local chemical works.

Pennsylvania

CHESTER.—The Cellulose Silk Co. of America is planning for the early installation of machinery at the local Patterson mills, recently acquired, for the manufacture of artificial silk under an improved copper-ammonia process. The property is located on Sixth St., fronting on the Chester River, comprising a number of 2-story buildings with a total of 50,000 sq. ft. of floor area. M. H. Avram, head of M. H. Avram & Co., Inc., 360 Madison Ave., New York, is president.

PITTSBURGH.—The International Cork Co. has leased the 3-story building, 25 x 70 ft., at 511 First Ave., near Grant St., for a local works.

PHILADELPHIA.—The B. F. Goodrich Rubber Co., Akron, O., has leased the plant of Reyburn Mfg. Co., 23d St. and Allegheny Ave., comprising about 100,000 sq. ft., for a local plant. The lease is for a period of years and totals \$250,000. The Reyburn company, manufacturer of tags, is building a new plant at 32d St. and Allegheny Ave., and plans to occupy the structure at an early date. It will total about 250,000 sq. ft. in manufacturing area.

Texas

WICHITA FALLS.—The Keystone-Ranger Producing & Refining Co., Pittsburgh, Pa., is planning for extensions in the local plant of the Southwestern Producing & Refining Co., recently acquired. The plant has a capacity of about 1,000 bbl., and this will be increased.

CASTROVILLE.—The Gulf Portland Cement Assn., recently organized with a capital of \$300,000, is planning for the construction of a large cement manufacturing plant in this section. The company is headed by L. C. Ihnken and John J. Shorp, Castroville; and W. S. Campbell, San Antonio, Tex.

WICHITA FALLS.—J. G. Kilgore and O. B. Manross are organizing a company to construct a new oil refinery at Wichita Falls, with initial capacity of about 500 barrels.

FORT WORTH.—The Invincible Oil Corp. is planning for a bond issue to total about \$3,000,000. A portion of the proceeds will be used for the erection of an addition to the present oil refinery. George W. Lull is president.

Virginia

RICHMOND.—The Master Products Co., 1107 East Cary St., recently organized, has acquired a local building for its proposed new plant for the manufacture of chemical specialties, including insecticides and other products. Machinery will be installed at an early date. The company is capitalized at \$50,000. E. R. Aiken is president.

West Virginia

ELLENSBORO.—The Insulite Co., manufacturer of molded composition products, has arranged for the establishment of a new local plant, 80 x 160 ft., and for which a contract recently has been let. A power house will also be installed in connection with the works. Considerable machinery will be installed for general production. Edward J. White is president and manager.

BARBOURSVILLE.—The Barbooursville Clay Mfg. Co., is considering the rebuilding of the portion of its plant, destroyed by fire on April 13.

HUNTINGTON.—The Specialty Glass Co., recently organized, will construct a new local plant for the manufacture of bent glass products, such as automobile headlights, etc. Glass presses, cutting machinery and other equipment will be installed. E. W. Miller is vice-president and treasurer; William Shaw is manager.

Wisconsin

MILWAUKEE.—The L. J. Mueller Furnace Co., 197 Reed St., has awarded a contract to Paul Riesen & Sons, 1018 Humboldt Ave., for the erection of a 1-story plant at Fifteenth and Oklahoma Sts., 60 x 100 ft., to be equipped as a japanning works.

Industrial Notes

THE NATIONAL ASSOCIATION FOR THE PROTECTION OF AMERICAN RIGHTS IN MEXICO has removed its offices to 32 Bway, New York City.

THE EQUITABLE EQUIPMENT Co., a new concern, has just completed its organization for the purpose of handling locomotives, cars, machinery of all kinds, etc. Offices are located at 411 Whitney-Central Bldg., New Orleans, La.

DWIGHT P. ROBINSON & Co., INC., has recently opened branch offices in Montreal, in the Dominion Express Bldg. Alexander C. Barker, vice-president, is in charge of the office.

THE AMERICAN AMINO CORP., Garwood, N. J., has just completed its plant at Matawan, N. J., and is ready to submit samples and dyestuff intermediates.

THE RUGGLES-COLES ENGINEERING Co. has moved from 50 Church St. to 120 Bway, New York City.

FRANK D. CHASE, INC., Chicago, Ill., has just completed work on four buildings of the new West Milwaukee plant for the Chain Belt Co. of Milwaukee.

C. LORENZ AKTIENGESSELLSCHAFT, Berlin, has purchased the Weld-Barfield patent rights for Germany, Poland and the former Austria-Hungary. Messrs. Lorenz have already placed an order with Automatic & Electric Furnaces, Ltd., for various parts to complete nearly 100 furnaces.

OHIO EXPORT & TRADING Co. has established its main office at 33 West 17th St., New York City, maintaining a branch office at its former headquarters in Cleveland. O. J. H. Schmidt, manager of the chemical equipment department, has his headquarters in the New York office.

THE NEW ENGLAND TANK & TOWER Co., Everett, Mass., opened a branch office on March 7 at 30 Church St., New York City. A. E. Hall, vice-president of the company, is in charge.

THE BLAW-KNOX Co., Blawnox (Pittsburgh), Pa., on April 1 opened a new sales territory in the Southwest, with headquarters in Kansas City, Mo. The new office, which is located in the Interstate Bldg., is in charge of R. B. Randall, formerly connected with the company's Chicago office, who will be known as manager of the Southwestern territory.

AMERICAN HINGE Co., incorporated under the laws of Oklahoma, has established a manufacturing plant at Memphis, Tenn. The modern cement and glass factory building, constituting the future plant, is now being constructed on the corner of Maple and Dunlap Sts. The approximate cost is \$100,000. The company will manufacture a complete special line of hinges, hardware and mining specialties. All material will be furnished by the Memphis Iron & Steel Co., which has recently established a new rolling mill in Memphis. The capacity of the new plants will be 10,000 hinges per day.

METALS COATING Co. OF AMERICA, which issues licenses for the use of the Schoop metal spraying process, is now located at 495-497 North Third St., Philadelphia, Pa. Richard L. Binder is president of the company.

ARTHUR D. LITTLE, INC., Cambridge, Mass., is publishing as a reprint from the *Paper Trade Journal* the Bibliography of Papermaking Materials which was compiled by Clarence Jay West. This will be a pamphlet of 170 pages. While the company is desirous of furnishing this to all members of the Technical Association of the Pulp and Paper Industry, the cost of production makes it advisable that it be sent only to those members who are really interested in the question of fibers, other than wood, used for the manufacture of paper. If, therefore, a copy of this bibliography is desired (Bibliographic Series No. 6) a postcard addressed to the firm will insure its receipt.

THE AUSTIN MACHINERY CORP. furnishes the information that on March 22 fire destroyed its Winthrop Harbor, Ill., plant, and while extensive damage was done there will not be any interference with production and prompt delivery of Austin trenching machines, backfillers, building mixers, pavers, draglines and shovels, as practically all lines of Austin machinery are also being built at the plants at Muskegon, Mich., as well as at the former plant of the Toledo Bridge & Crane Co., Toledo, O. It has been arranged to have the plants at Toledo and Muskegon increase their stock production orders to take care of the shortage which would otherwise occur through the loss of the Winthrop Harbor plant.

THE PEASE LABORATORIES, INC., 39 West 38th St., New York City, announces that Dwight Tenney, chief engineer of the Franklin Baker Co. of New York, has become associated with it as head of the newly organized department of engineering. He will continue his connection with the former company as consulting engineer, having charge of all technical development work.

THE JOSEPH DIXON CRUCIBLE Co. announces that Herbert L. Hewson has been placed in charge, as special representative, of the sale of crucible factory products in Ohio, southern peninsula of Michigan, Pittsburgh and adjacent cities and towns. Mr. Hewson first became associated with the Dixon company in 1909 in the San Francisco office.

THE STIMPSON EQUIPMENT Co., Salt Lake City, Utah, announces that Clinton Clark has been transferred to the New York office, Grand Central Palace.

SKINNER, SHERMAN & ESSELEN, INC., 248 Boylston St., Boston, Mass., has been organized and equipped to furnish counsel on all matters relating to the application of chemistry and biology to industrial operations. The new corporation has acquired the business and good will of the Boston Bio-Chemical Laboratory and will hereafter direct its activities. Prof. Samuel C. Prescott has been retained as consulting industrial biologist, and Burton G. Philbrick as laboratory director. The personnel of the corporation comprises Hervey J. Skinner, Herbert L. Sherman and Gustavus J. Esselen, Jr.

THE ENGINEERING BUSINESS EXCHANGE, New York City, announces the opening of a Southeastern branch, with offices in the McLachlen Bldg., Washington, D. C., with Marshall O. Leighton as director. Mr. Leighton was for twelve years one of the officers of the U. S. Geological Survey. Associated with Mr. Leighton will be A. C. Oliphant, who has been active in the work of Engineering Council's National Service Committee.

F. J. RYAN & Co., Philadelphia, announces that it has secured control of engineering, sales and installation of all Mirco fuel-fired equipment of the Lancaster Iron Works, Lancaster, Pa. Sales and engineering headquarters are at Philadelphia; manufacturing headquarters are at Lancaster, Pa.; New York office is retained at 501 Fifth Ave. W. W. Posey, president of the Lancaster Iron Works, has been elected a director of F. J. Ryan & Co., and A. C. Scully, secretary and treasurer of the Lancaster Iron Works, has been elected a director and treasurer.

THE BROWN HOISTING MACHINERY Co., Cleveland, O., announces the opening of a Southern office for Texas, Louisiana, Mississippi, Alabama, Georgia and Florida to be located at 530 Whitney-Central Bldg., New Orleans; Charles H. White, manager.

THE TECHNICAL SERVICE Co. has been organized, with offices in the Colonial Bldg., Allentown, Pa., to handle chemical and metallurgical problems and to provide sales service in technical equipment, materials and supplies. This company was formed by Edgar S. Genstein, who was previously metallurgist for the Treadwell Engineering Co., Easton, Pa., in chemical and metallurgical work during several years with the U. S. Navy and Army Departments.

O. S. SLEEPER & Co. announces its formation for the purpose of placing on the market a line of drying and chemical apparatus of improved design. The members of the company recently resigned from the engineering staff of the Buffalo Foundry & Machine Co. and include O. S. Sleeper, president; H. E. Neubauer, vice-president, and C. B. Brown, secretary and treasurer. Mr. Sleeper was chief engineer of the Buffalo County & Machine Co. for fourteen years. This company is prepared to furnish a line of vacuum self driers, vacuum rotary driers, direct heat driers, flaking machines, crystallizers and special apparatus.

M. P. BURT & Co. has established offices as mechanical engineer at 206 Falls Bldg., Memphis, Tenn. Included in the personnel of the new company are Milton T. Burt, mechanical engineer; J. Paul Gaines, civil engineer, and Louis G. Carlisle, architect. The company will specialize in packing house and cold storage designing and consultation on power and operating costs. Mr. Burt was formerly with the Memphis Packing Co.

THE LIMESTONE PRODUCTS Co., incorporated under the laws of Missouri, recently organized to operate quarries at Black Rock, Ark., has established headquarters in the Randolph Bldg., Memphis, Tenn. John G. Woodruff of Springfield, Mo., is president, and R. F. Alessi is secretary.

THE INTERNATIONAL PULVERIZED FUEL CORP. announces that since April 20 its general offices were located in the National City Bldg., 17 East 42d St., New York City.

THE SUPERHEATER Co. announces that on May 1 its general offices will be moved from 30 Church St. to 17 East 42d St., New York City.

THE INTERNATIONAL TRADING Co., LTD., announces the removal on May 1 to its former address, 60 B'way, New York City.

VICTOR T. GOGGIN, late New England sales manager of Fred T. Lev & Co., Springfield, Boston and New York, has severed his connection with that concern to associate himself as contracting engineer with Dwight P. Robinson & Co., Inc., New York.

O. L. MOORE, chief cement inspector of the Universal Portland Cement Co., has been appointed engineer, inspection bureau, with headquarters at 210 South La Salle St., Chicago.

THE AIRCO organization (Air Reduction Sales Co.), manufacturer of oxygen, acetylene and welding and cutting apparatus, moved its executive offices on May 1 to 342 Madison Ave., New York City. Coincident with the announcement of the general office change is another to the effect that the New York district office is located at the Airco factory, 191 Pacific Ave., Jersey City, N. J., since May. Announcement is also made that the Air Reduction Co. has obtained control of the National Carbide Corp. of Virginia, with a new plant at Ivanhoe, Va.

THE GAGE PUBLISHING Co., INC., publisher of *Electrical Record*, *Electrical Export* and *Raw Material*, located at 114 Liberty St., New York, for twenty-three years, has moved its executive and editorial offices to the Printing Crafts Bldg., 461 Eighth Ave., between 33d and 34th St.

THE EMPLOYERS MUTUAL INSURANCE Co., 61 B'way, N. Y., announces the appointment of E. C. Jacobs, formerly chief chemical risk inspector of the New Jersey Rating and Inspection Bureau, as insurance expert in charge of the inspection and underwriting of chemical risks.

THE HARRY M. HOPE ENGINEERING Co., of Boston, has established offices in the Dominion Express Bldg., Montreal, to handle its Canadian business. George W. Saunders, formerly with S. Pearson & Sons, London, is Canadian manager.

SCHWARZ LABORATORIES, analytical and consulting chemist, advises its clients of its removal on May 1 to 113 Hudson St., New York City.

THE THERMAL SYNDICATE, LTD., manufacturer of fused silica ware for chemical plant and laboratory use, announces its removal on May 1 to the New Borden Bldg., 350 Madison Ave., New York City.

THE CONVEYORS CORP. OF AMERICA, Chicago and New York, announces the appointment of Robert B. M. Wilson as sales engineer of the Chicago district. With him will be associated E. M. Wolfe. Headquarters will be maintained in the corporation's main office at 326 West Madison St., Chicago.

THE ELECTRIC FURNACE Co., Alliance, O., has just installed three Baily electric brass-melting furnaces of different size and capacity. The Bagley & Sewall Co., Watertown, N. Y., has installed a 50-kw. electric furnace with 500 lb. hearth capacity, the Alliance Brass & Bronze Co. a 75-kw. furnace with 800 lb. capacity, and the Empire Brass Works of London, Ont., a 105-kw. furnace of 1,500 lb. hearth capacity. All these furnaces are to melt yellow and red brass alloys. It is also announced that the Lorain Steel Co., Johnstown, Pa., is installing a 200-kw. Baily electric furnace for heat-treating railroad bolts and similar parts. This furnace is of the continuous pusher type with motor-operated control mechanism and will have a capacity sufficient to heat-treat 14 tons of material per day.

ELECTRIC FURNACE CONSTRUCTION Co., Philadelphia, Pa., has received an order from the Sociedad Espanola de Construcción Naval for a new design of electrically heated car-type annealing furnace for heat-treating large steel ingots and forgings. It will be 6.8 m. long by 4.75 m. wide by 4.14 m. high, and will heat a charge of 60 tons of steel to 1,700 deg. F. every 24 hours. T. H. Watson & Co., Ltd., Sheffield, England, and the Electric Furnace Construction Co., Philadelphia, announce that arrangements have been made with the General Combustion Co., of Canada, Ltd., New Kirks Bldg., Montreal, to handle, build and sell their various electric smelting, melting and refining furnaces in Canada. The Canadian rights of the Greaves-Etchells type of furnace are also included in the arrangements made.

New Companies

THE CENTRAL PAPER Co., Newark, N. J., has been incorporated with a capital of \$50,000 to manufacture and deal in paper products. The incorporators are Benjamin S. Berkowitz, Morris W. Shapiro and Louis Weiss, 148 Mulberry St.

THE IMPERIAL BEARING BRONZE Co., Flushing, L. I., has been incorporated with a capital of \$20,000 to manufacture brass and bronze products. The incorporators are L. Osabon, J. M. Partmann and S. O. Wood, Jamaica, L. I.

THE MISSOURI OXIDE & CHEMICAL Co., New York, N. Y., has been incorporated under Delaware laws with a capital of \$800,000 to manufacture chemicals and chemical byproducts. The company is represented by Arthur W. Britton, 65 Cedar St.

THE EASTERN TABLET Co., Boston, Mass., has been incorporated with a capital of \$775,000 to manufacture paper products. The incorporators are Alexander W. Murray, Wellesley Farms, Mass.; Marcus E. Mahon, Quincy, Mass.; and Ray Henry, Cambridge, Mass.

THE RIVERWAY MFG. CORP., Cambridge, Mass., has been incorporated with a capital of \$50,000 to manufacture chemicals and byproducts. The incorporators are A. Hollander, Brookline, Mass.; Cyril M. and J. Hollander, Boston.

THE PABST CHEMICAL CORP., 324 Sherman St., Chicago, Ill., has been incorporated with a capital of 200 shares of stock, no par value, to manufacture chemicals and affiliated products. The incorporators are William W. Allan, George W. Andress and Theodore Harbeck.

THE HOLYOKE GUMMED PRODUCTS Co., Holyoke, Mass., has been incorporated with a capital of \$100,000 to manufacture paper, strawboard and kindred products. The incorporators are Charles F. Moriarty, Nashua, N. H.; Martin J. Judge and Maurice J. Moriarty, South Hadley Falls, Mass.; and Charles B. Dunbar, Holyoke.

HANSON, DUNN & Co., INC., Providence, R. I., has been incorporated with a capital of \$20,000 to manufacture soaps and kindred products. The incorporators are Louis W. and John F. Dunn, and Samuel Hanson, 11 Evergreen St., Providence.

THE VAN SICLEN CHEMICAL LABORATORIES, INC., Brooklyn, N. Y., has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are J. T. Rep-ton, N. Handler and W. H. Birken, I. Berson, 16 Court St., represents the company.

THE WINAMAC CEMENT PRODUCTS Co., Winamac, Ind., has been incorporated with a capital of \$25,000 to manufacture cement specialties. The incorporators are Chris Hansen, John Kruzick and George Kurzick, Winamac.

THE FLEXIBLE CORK Co., Jersey City, N. J., has been incorporated with a capital of 7,400 shares of stock, no par value, to manufacture cork products. The incorporators are H. A. Black, Alfred F. McCabe and John R. Turner, 15 Exchange Pl.

THE EDWARD R. BULE CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of \$30,000 to manufacture soaps, cleaning preparations and other chemical products. The incorporators are Edward R. Bule, C. F. Newinger and V. Mast. The company is represented by Lee, Aron & Wise, 7 Dey St.

THE KANE OIL REFINING Co., Brooklyn, N. Y., has been incorporated with a capital of \$25,000 to manufacture refined oil products. The incorporators are W. A. Kane, Sr. and Jr., and H. S. Cook, 38 Park Row.

THE OIL & SUPPLY Co. OF ILLINOIS, 116 South Michigan Ave., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture refined oils. The incorporators are H. O. Nottingham, Frank B. Page and James E. Hauronic.

THE C. M. CARROLL PAPER Co., New Bedford, Mass., has been incorporated with a capital of \$25,000 to manufacture paper products. Charles M. Carroll, 50 Page St., is president and treasurer; G. E. and Milton E. Carroll are directors.

THE STAR OIL Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are W. A. and E. M. Mathias, and R. E. Burbank, Los Angeles.

THE PURE AIR CORPORATION, New York, N. Y., has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are S. G. Geler and J. S. Friedman, 277 B'way.

THE ROBERT WYSLEY Co., 91 River St., Hoboken, N. J., has been organized to manufacture chemicals and affiliated products. Nicholas Noggi heads the company.

THE UNIVERSAL CHEMICAL Co., Richmond, Va., has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are H. L. Jones, Norfolk, Va.; and J. McD. Woolford, Richmond.

THE DROWN SPECIALTY Co., Worcester, Mass., has been incorporated with a capital of \$10,000 to manufacture paper products. William L. Drown is president; and Oscar L. Drown, 6 Field Way, treasurer.

THE UNIVERSAL SHALE PRODUCTS Co., Buffalo, N. Y., has been incorporated with a capital of \$500,000 to manufacture refined mineral oil products. The incorporators are A. Adamozak and J. Janowski. Falk, Phillips & Schlenker, Morgan Bldg., represent the company.

THE LIBERTY PAINT Co., 1400 First National Bank Bldg., Chicago, Ill., has been incorporated with a capital of \$20,000 to manufacture paints, oils, etc. The incorporators are Frank B. Page and associates. Winston, Strawn & Shaw, address noted, represent the company.

THE CROWN DIE CASTING Co., Detroit, Mich., has been incorporated with a capital of \$25,000 to manufacture die castings and kindred metal products. The incorporators are R. Frank Ward, Mt. Morris, Mich.; John F. Goude and V. E. Thompson, Flint, Mich.

THE PEEL CHEMICAL CORP., New York, N. Y., has been incorporated with a capital of \$200,000 to manufacture chemicals and chemical byproducts. The incorporators are A. B. Johnson, R. P. Dicks and A. David, Platt & Field, 120 B'way, represent the company.

THE MODERN LUBRICATING Co., Minneapolis, Minn., has been incorporated with a capital of \$100,000 to manufacture lubricating oils and kindred products. The incorporators are A. N. and D. Peever, and George H. Clarke, Minneapolis.

THE HIDE & LEATHER Co., Boston, Mass., has been incorporated with a capital of \$200,000 to manufacture leather products. Ralph W. Dunbar is president, and Harrison M. Davis, 75 Ames Bldg., treasurer.

THE PECOS VALLEY REFINING Co., Los Angeles, Cal., has been incorporated with a capital of \$100,000 to manufacture refined oils. The incorporators are L. K. Adams, John C. Gillkam and George W. Davis, Los Angeles.

THE BOHEMIA BRICK & TILE Co., Houston, Tex., has been incorporated with a capital of \$125,000 to manufacture brick, tile and other burned clay products. The incorporators are A. T. Eddington, Otto Jetal and James Pokorny.

THE AMERICAN CELUTEX CORP., New York, N. Y., has been incorporated with a capital of \$200,000 to manufacture celluloid and other composition products. The incorporators are A. Burke, I. L. Goldberg and C. S. Aronstan, 100 B'way.

THE MERLE SEARS PAPER BOX Co., 740-42 Main St., Danville, Ill., has been incorporated with a capital of \$60,000 to manufacture paper cartons, containers, etc. The incorporators are H. N. and Merle Sears, and George D. Johnson.

THE PRODUCERS' PETROLEUM Co., Duncan, Okla., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are John O'Donahue, W. M. McGregor and C. E. McCutchen.

THE BELCO DRUG & EXTRACT Co., 790 Broad St., Newark, N. J., has been incorporated with a capital of \$25,000 to manufacture chemicals, drugs, etc. The incorporators are Samuel M. Hollander, S. Kneip, Newark; and E. Fairhurst, Kearny, N. J.

THE HUNTINGTON-PACIFIC OIL & REFINING Co., Los Angeles, Cal., has been incorporated with a capital of \$250,000 to manufacture petroleum products. The incorporators are J. J. Eiseman, J. H. Roth and George E. Benson.

THE LOWRY MFG. Co., Winchester, Ky., has been incorporated with a capital of \$10,000 to manufacture chemicals, washing powder and kindred products. The incorporators are E. A. and S. M. Lowry, and Edward C. Epperson, Winchester.

THE CHIEF CHEMICAL LABORATORIES, INC., Brooklyn, N. Y., has been incorporated with a capital of \$6,000 to manufacture chemical specialties. The incorporators are S. Krasner and H. Shorenstein. Caldwell & Polhemus, 50 Church St., New York, represent the company.

THE STANDARD CLAY Co., Brazil, Ind.,

has been incorporated with a capital of \$300,000 to manufacture bricks, tile and other burned clay products. The incorporators are Albert F. Price and Edwin T. Norris, Brazil; and John H. Wright, Indianapolis, Ind.

THE RELIABLE GLASS Co., 1816 West Division St., Chicago, Ill., has been incorporated with a capital of \$6,000, to manufacture glassware. The incorporators are Harry Resnick, Samuel Sless and Jacob Schulemsohn.

THE FAIRMONT-SOMERSET OIL Co., Fairmont, W. Va., has been incorporated with a capital of \$200,000 to manufacture petroleum products. The incorporators are Osman E. Swartz, A. J. Colburn and W. R. Dougan, Fairmont.

THE GREENPORT BRICK CORP., Greenport, N. Y., has been incorporated with a capital of \$300,000 to manufacture brick and other burned clay products. The incorporators are J. Briskman, S. Bitterman and E. R. Greenstein. Bitterman & Hecht, 305 B'way, New York, represent the company.

Coming Meetings and Events

AMERICAN ASSOCIATION OF ENGINEERS will hold its seventh annual convention at the Hotel Lafayette, Buffalo, N. Y., on May 9, 10 and 11.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

AMERICAN ZINC INSTITUTE will hold its annual meeting in St. Louis May 9 and 10.

COLORADO SCIENTIFIC SOCIETY, Denver, Col., will hold its 343d regular meeting May 7, 1921, in the Colorado State Museum Bldg., Denver. Arthur J. Hoskins will address the meeting. His subject is "Colorado's Oil-Shale Industry."

BRITISH IRON AND STEEL INSTITUTE will hold its spring meeting May 5 and 6, at the Institution of Civil Engineers, Great George St., S. W. 1, London, England.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-eighth annual convention at the Greenbrier Hotel, White Sulphur Springs, W. Va., the week beginning June 20.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 842 Broad St., Newark, N. J., the second Monday of every month.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month; except June, July, August and September.

TANNERS' COUNCIL OF THE UNITED STATES will hold its annual spring convention at the Hotel Traymore, Atlantic City, May 5 and 6.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: May 6, American Chemical Society, Nichols Medal award; May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Meetings of Chemists And Electrochemists

THE spring meetings of the American Electrochemical and American Chemical societies, which are reported in this issue, afforded the usual opportunity for discussing technical subjects, exchanging opinions and renewing acquaintances. The electrochemists, being smaller in number and more flexible in organization, adapted themselves to their surroundings at Atlantic City and indulged in competitive sports and recreation for two afternoons. Apparently this admixture of pleasure to the technical sessions was regarded as a successful experiment, because the directors voted to hold the fall meeting at Lake Placid, N. Y., September 29 and 30 and October 1. The technical feature of the Atlantic City meeting was a Symposium on Corrosion, which is fully reported elsewhere. While no new or startling facts were brought out, additional data and observations were recorded to verify or refute some of the unsettled theories which have been advanced to account for the varied phenomena of corrosion. An important action of the directors was a decision to hold a Symposium on Electrothermics annually at the spring meeting. With this topic definitely scheduled thus far in advance, it should be possible to prepare excellent programs embodying not only the results of operation but also of experiment and research. The election of ACHESON SMITH to the presidency of the society will insure a lively interest in the first symposium on this subject next spring.

The chemists met at Rochester and it is worth recording at this point that the meeting was marked by freedom from confusion and excellent arrangements on the part of the local committees. If we were to emphasize the most distinctive general feature of the convention, we should mark the presidency of Dr. EDGAR FAHS SMITH and the enlivened recognition of the need of fundamental research. Dr. SMITH is an unusual presiding officer. He speaks with such rare grace, with such sanity and good nature, that the audience hardly recognizes how closely it is held in leash. If it starts to run away from a subject, or to give way to useless discussion, he brings it back with some droll comment that does the work desired under a ripple of laughter. He adds also a quality of dignity to that of affability which is reflected in the tone of the whole meeting. The other noteworthy feature is the apparent earnest resolution of the members to declare the need of fundamental research. It presses in many places where even laboratory work in one field or another is at an *impasse* because certain facts, which should be known are not available and the smaller laboratories have not the facilities to determine them. That incompetent and underdone chemists should be seeking and finding other occupations is in the nature of things and generally approved, but the disposition of short-sighted men in

industry to dismantle established research laboratories in the interest of false economy is regarded as a menace to national progress.

We have no sympathy with camp-meeting designations for serious assemblies, but if we must have a tag for the occasion at Rochester we should be disposed to call it the Sober Second Thought Meeting. It was more of a scientific colloquium than a traders' assembly, and yet it would have been more illuminating to traders who have "bought into" chemical industry than any number of Chamber of Commerce festivals of speech. The necessity of real chemical scholarship in industry as well as in academic life was repeatedly emphasized, and to miss this point would have required a mind either unusually dull or supersaturated with arrogant vanity.

The general meetings were unusually constructive and informing. Senator WADSWORTH and Congressman LONGWORTH, who spoke, have a vision of the function of chemistry in national life. We cannot recall any time when such a direct, frank and confidential communication from a lawmaking body was made to the society as was presented by both these gentlemen. Certainly no political constituency could have asked or received a more direct pledge from its leader than was given to the society by Congressman LONGWORTH when he reiterated the assurance that the dye and chemical industry would be given adequate protection in the forthcoming tariff schedule.

An interesting criticism was made by Dr. ALSBERG in one of the meetings to the effect that there is too much tacit agreement at gatherings. Papers are not attacked enough. If a member gives his records and these seem wrong, somebody is likely to get up and ask the speaker how he has reached his conclusions, and the answer is not likely to contain much more information than that these were concluded from preponderance of evidence. The questioner sits down unconvinced, and the speaker is not called on to make a proper defence of his work. This has the defect of inadequate censorship, and tends to permit defective information and shallow reasoning to go on record. He intimated that we are too tender with one another, and that it is better to cause a little pain and to hurt the feelings of those who persevere in error than to permit an error to endure. We think he is right. In this respect the chemists can learn a lesson from the electrochemists, with whom the frankest criticism is the prevailing custom. Debatable and controversial questions are not handled with gloves in that organization.

We are glad to report an action by several of the sections and divisions that will have a tendency to make future meetings more interesting and profitable. It is plainly recognized that the program as now constituted is appalling rather than attractive on account of the large number of papers scheduled for presentation and the difficulty experienced by the average attendant in

discriminating between good, bad and mediocre offerings. Under the spur of Mr. HOWE's keen criticism the Division of Industrial and Engineering Chemistry voted to appoint a committee to pass on all papers before they are accepted for the program. Papers must be in the hands of the committee at least two weeks before the meeting and they will be accepted, rejected or liberally blue-penciled according to their merits. In addition to this the chairman will decide whether papers shall be read in abstract or *in extenso* and will have power to limit discussion on subjects in which only a few are interested. Similar tendencies are noted in the Division of Physical and Inorganic Chemistry and the new Petroleum Section, both of which will issue to their members in advance of the meeting a full set of abstracts of papers admitted to the program. These are hopeful, if somewhat sporadic, signs of improvement—experiments out of which the parent society will doubtless evolve a unified plan for all sections and divisions.

A Suggestion To Authors

THIS is in the nature of a personal chat with those excellent and estimable persons who read papers at scientific society meetings. Without their zeal and enthusiasm we would have no formal technical programs, and but for their personal interest in science we would not have nearly so wide a dissemination of technical knowledge. Curiously enough, however, they frequently lack the quality of salesmanship which would greatly enhance their value to their audience. They do not know how to present the ideas which they have carefully recorded after painstaking thought, research and investigation. About twice a year following the spring and fall seasons of scientific and technical conventions, we have been tempted to express our feelings on this subject, not in unkind criticism, but by way of friendly advice and suggestion. Probably this is because it falls to the lot of editors not only to attend but also to report a great many meetings, and consequently their feelings on this subject are more intense than are those of the average attendant.

In the first place there are few technical papers that will bear reading verbatim to an audience. The literary style in which they are couched is far better adapted to quiet perusal in printed form. What the audience is most interested in may be phrased expressively, if inelegantly, by the query, "What's it all about?" In other words, there is, or should be, an important feature, result or conclusion which summarizes the author's contribution and which can be told in simple language in conversational style. It is not expecting too much of an author to ask that he shall be sufficiently familiar with his subject to be able to review and summarize his paper extemporaneously and relieve his audience of the impossible task of following him through a formal reading. This is particularly true when chemical equations, mathematical formulæ or tabulated data are to be presented. A few lantern slides and a five-minute explanatory talk will frequently tell the whole story better than a twenty-minute formal reading which leaves the audience confused. It is a matter of simple observation that the author who best transmits his ideas to his audience does so through these simple expedients; and it may be worth noting that our convictions in the matter are shared and openly expressed by those thoughtful persons trying to get the most out of their attendance on conventions.

Army's Nitrogen Policy Determined

WE NOTE with gratification that Secretary WEEKS has finally determined the nitrogen policy of the War Department and that his ruling is practically in accordance with the editorial suggestions made in CHEMICAL & METALLURGICAL ENGINEERING, April 27, 1921. The Fixed Nitrogen Research Laboratory, in American University in Washington, is to be continued, and Nitrate Plants Nos. 1 and 2, at Sheffield and Muscle Shoals, Ala., respectively, will be retained under Army control in the most economical stand-by condition. The Secretary's decision is eminently satisfactory from all points of view—fundamental scientific research, industrial development and military preparedness.

More Business In Chemistry

A YOUNG chemist who is a real one and whom we like as a companion lately criticized us technical journals for accepting the advertisement of a business institute. "Why," he asked, "do you want me to study business and salesmanship and commercial law and such things when my subject is chemistry? Being engaged in technology, I have to address myself to business problems at the expense of my information in chemistry. My proper subject for my spare time should be and is the fundamentals in science; the philosophy of the subject, the general principles, the work of THEODORE RICHARDS, or IRVING LANGMUIR, of SVEDBERG, and of the men who look ahead. Chemistry is not a dinky little thing that one studies and then *has*. No chemist is a chemist when he graduates; or at least very few are. Why should I study book-keeping when I don't want to keep books, or salesmanship when I don't want to sell? I have more important work in my own field. Chemistry is too big and too deep to make jacks of all trades of those who follow it."

Now all knowledge is not for all men nor is every advertisement in a magazine intended for every reader thereof. The place for our friend whom we quote is in the laboratory rather than in the works, and we hope to see him some day an honored professor of chemistry in an institution of learning. He has a leaning toward research in pure science, and that is where he should be engaged. But in technology we need more and better business understanding. Thorough training in and familiarity with the principles of science is the first requirement, but in technology there is an equal need of good, sound, business sense. Indeed, we can't get along without it.

The fact is we must have sense about business just as we must have sense about chemistry. When over a score of years ago the Yale Corporation promoted the greatest teacher of physiological chemistry that this country has known to be director or dean of the Sheffield Scientific School, we had a fit of indignation that has lasted until this day. Teaching is the greatest of all the arts; it is paid less, but is, in point of fact, more important than administration. The loss to medicine and biology by the withdrawal of Prof. CHITTENDEN from teaching was too great to be forgiven, even in so distinguished a body as the Corporation of Yale University. Their fault was a lack of business sense; they wanted a good administrator, Dr. CHITTENDEN was the only one they could find easily, and according to the iron-bound Yale traditions it was the only way they could provide him with the proper compensation.

Business sense means a sense of co-ordination; the ability to put the right people in the right places; the capacity to plan ahead so that the desired purpose may be achieved. It means economy in planning just as applied chemistry means economy in technology. They go together. There's every reason in the world why our chemists should have that vision of human reactions that we call business. It will help more than anything else to put an end to fake chemistry and establish chemists in the eyes of business leaders and the public.

Development Possibilities Are Unlimited

WHAT is the most hopeful fact in this period of industrial depression? Undoubtedly it is that the usual obsession has not spread that "the country is overdeveloped." That has been a dominant thought in every previous industrial depression. Each business man, reasoning from the phenomena in his own industry, has concluded that he had too many competitors. There were too many miles of railroad, and too many factories making this thing or that. Machinery had been built to do all the work and all the machine shops could hope for was employment in keeping up the machinery already supplied. That is not the common thought today.

They say human nature does not change, and that may be true in a sense, but the style of thought and the viewpoint do change. Somewhat over a century ago the crowd jeered at ROBERT FULTON because his new steamboat broke down. Today a typical American crowd would be sorry. The female of the species has been offered more in the small electric motor than the male, as an individual. She has her electric-driven vacuum machine, washing machine, wringer and ironer. The male has his electric fan in the office, and that is about all. The male's lawn mower is food-propelled, depending on weight for traction, with the coefficient of traction varying inversely with the cutability of the grass. If a lawn mower with an electric-driven cutter is put on the market the first users will not be jeered by their neighbors. The neighbors will ask, "Where do you get those things?"

Repeatedly it has been proved that the country cannot be overdeveloped and at last men have learned the lesson, partly at least, supplied by recorded history. At a given time there may be too much of a material offered, or too many of a given device, for the people to buy, but that is because they have not been working hard enough or have not utilized other economical materials or devices to enable them to save the necessary money. That is what men do in every industrial depression or in its latter part.

The obsession that "the country is overdeveloped" did not make its appearance with recent industrial depressions, but has been chronic for three-quarters of a century, or since the introduction of farm machinery released a large percentage of the population from agriculture to engage in manufacturing. Each time, when the depression ended, it was seen that the country was not developed too much, but that instead it had fresh possibilities. What occurred was that prices and costs went too high and people became disinclined to buy. As the people curtailed their purchases they produced a condition that enlarged the prospect of prices and costs going lower and thus the tendency to abstain from buying was encouraged, the influence

being cumulative, until the shake-out became sufficient to justify making a fresh start.

To-day one does not hear the cry, to any extent, that "the country is overdeveloped." Instead, people are simply saying prices are too high, wages are too high, costs are too high, and when they find their proper level business will go forward. Public thought has not, as a millstone around its neck, the notion that everything worth doing has already been done and there is little left for the future to do.

Men will be quite ready to take hold when the readjustment in prices, wages, costs, has been completed. They are anxious to take hold. They are not afraid that the work has already been done. Anyone can see ample prospects of work and development. Under proper financial and industrial conditions we can profitably electrify our railroads, stop the consumption of over 90 per cent of our bituminous coal without recovery of byproducts and the movement of hundreds of millions of tons of coal a year over railroads (when the high-tension electric line is a vastly greater improvement in transportation than was the oil pipe line of nearly half a century ago), reduce the air, noise and heat leaks in our dwelling places and do a thousand other things, not forgetting to provide the electric-driven grass cutter already mentioned. The public has sensed the situation rightly. The country is not overdeveloped; it merely needs to readjust some things.

Interim Protection For the Dye Industry

IT HAS BEEN a matter of some speculation and no small degree of anxiety to foresee how the dumping of dyes in this country could be prevented in the interim between the declaration of peace with Germany and the passage of tariff legislation. The first proposal was to attach an amendment to the Knox peace resolution, extending the powers of the War Trade Board Section of the Department of State, which now regulates imports of dyes from Germany. This possibility, however, was eliminated when all amendments to the Knox resolution were rejected.

A much more hopeful prospect for quick and effective action, however, is seen in the proposal to handle this matter in the emergency tariff legislation. The Senate Committee on Finance is now considering an amendment to H.R. 2435, excluding from importation into the United States for a period of six months from the enactment of the legislation, sodium nitrite, coal-tar products and synthetic organic drugs and chemicals, unless the Secretary of the Treasury shall determine that such articles or satisfactory substitutes are not obtainable in the United States in sufficient quantities and on reasonable terms. In this event the prohibited articles may be admitted for consumption by an actual consumer in the United States within six months after receipt of the merchandise. The amendment further provides for the transfer of the personnel, records and activities of the War Trade Board Section of the Department of State to the Department of the Treasury.

Emergency tariff legislation is not regarded seriously in many quarters, being looked upon as a political sop to agricultural interests. Apparently, however, it may become the most handy medium for accomplishing interim protection to the dye industry. It's an ill wind that blows nobody good.

British Chemical Industries

FROM OUR LONDON CORRESPONDENT

LONDON, April 14, 1921.

THE industrial and political situation completely dominates markets at the time of writing and even if, as is confidently predicted, the threatened railway and transport strike should be canceled, the recent revival has already been stopped and a considerable period will be required for recovery.

REPARATION ACT FAILS TO BENEFIT PURCHASERS OF CHEMICALS

The reparations bill has apparently not yet produced any "reparations" as far as the chemical trade is concerned. As foreshadowed in my last article, German exporters are demanding either payment in full, leaving the British importer to pay an equal amount in duty, or alternatively simply doubling their prices. In either case the consumer ultimately has to pay the tax, and it is becoming a question of whether the loss of trade will be sufficient to force Germany to make fresh proposals. Meanwhile the stocks of German chemicals imported or under contract prior to March 8 are fairly heavy, and some weeks must elapse before any appreciable rise in prices is to be expected.

FINE CHEMICALS INCLUDED IN PROTECTIVE MEASURE FOR KEY INDUSTRIES

In addition to optical and chemical glassware, tungsten, thorium, cerium, etc., the new "ways and means resolutions" to be discussed before inclusion in the finance act include "all synthetic organic chemicals (other than the dyes, etc., protected under the dyestuffs bill), analytical reagents, all other fine chemicals and chemicals manufactured by fermentation processes." Protection is to be given in the form of 33½ per cent customs duty for five years, and there is to be a similar duty in respect of "dumped" goods or those which are, owing to depreciated currency, offered at prices below the cost of profitable manufacture in the United Kingdom. The introduction of this legislation was unavoidably postponed by the industrial crisis, but already claims for the protection of other industries and goods and protests against the inclusion of others are being pressed on the government and on members of Parliament. It is understood that among others metallic magnesium is likely to be included, and that the fiercest controversy will develop in regard to the alleged inadequacy of the protection afforded. Meanwhile the fine chemical industry remains stagnant, many works being closed down or working on half time, while others are finding difficulty in raising further capital.

BRITISH DYESTUFFS CORPORATION DISMISSES ITS MANAGING DIRECTORS

Something of a sensation was caused by the announcement made at the annual meeting of the British Dyestuffs Corporation that the board of directors had decided to terminate the agreements with Sir Joseph Turner, who controlled the Huddersfield Works, and Dr. Herbert Levinstein. Although rumor had been rife in regard to Dr. Levinstein's retirement and in regard to lack of harmony and co-operation, the drastic steps now taken were quite unexpected. The board announced that pending unification of control under a single managing director a committee of three directors would form the executive, but it remains to be

seen whether a suitable "superman" will be forthcoming. Sir Harry McGowan, of Nobel Industries, retired from the board earlier in the year and the new directors appointed are Field Marshal Sir William Robertson, Sir William Alexander (formerly of Charles Tennant & Co.) and Vernon Clay, chairman of the Color Users Association. There is likely to be further controversy before the affairs of the corporation recover from what is considered to be an unnecessary muddle. Meanwhile the dyestuffs position remains practically unchanged and Sir H. V. Kilvert, a prominent member of the Manchester Chamber of Commerce, has been appointed chairman of the advisory committee under the dyestuffs act. There has been further delay in the appointment of the development committee.

BRUNNER, MOND TO INCREASE CAPITAL

It is announced that in addition to making suitable alterations in the articles of association of Brunner, Mond & Co. \$10,000,000 of additional 7½ per cent preference shares are to be issued in the near future. Work at Billingham synthetic ammonia factory is making good progress and part of the capital issue is no doubt required for that purpose. On the other hand Magadi soda shipments have begun, so that details of the prospectus are awaited with great interest. Wages of chemical workers are being reduced by many works, notably by Lever Bros. and the United Alkali Co., and owing to the depressed state of markets and the fall in the cost of living this tendency is likely to continue.

GENERAL NOTES

The report of the commission under General Hartley which visited German chemical factories last year is to be published at an early date and, unlike the corresponding report of the mission fathered by the Association of British Chemical Manufacturers, will be available to the general public. Like the report of the nitrogen committee, publication has been delayed so long that much of the matter will be out of date. Further details of the visit to Canada and the United States of the Society of Chemical Industry will shortly be available. It was felt that if possible the whole party should travel together on a "one-class" boat and fortunately the cancellation of the sailing of the *Megantic* will probably enable the president to sail with the rest of the party on the *Melita* on Aug. 12 for Montreal. It was hoped that the larger firms would send special representatives, but so far the response from this quarter has been very feeble, though it is perhaps too soon to judge of the final result. It now seems unlikely that the party will number more than sixty. Circulars have just been sent to all members of the engineering profession with regard to the proposed formation of an engineers' club with headquarters in St. James' St. It is stated that over 1,000 engineers have signified their intention of joining the new club, the subscription for which has been fixed provisionally at \$40 for town members. The promoters are seeking to include chemical engineers and others connected with the chemical industry, but it is felt that on account of the relatively high subscription the club will not be truly representative and is not likely to include the junior members of the profession. Sir William Pope is to address the members of the Chemical Industry Club next month and will probably deal with the further development of the scheme for central premises promoted by the Federal Council of Pure and Applied Chemistry.

Meeting of the American Electrochemical Society

Report of the Spring Meeting, April 21-23, 1921, at Atlantic City, N. J.—Business Session—Presidential Address—Summaries of the Technical Papers Presented, With Discussion of These Papers—Social Features

THE thirty-ninth General Meeting of the American Electrochemical Society took place at the Hotel Chalfonte, Atlantic City, April 21 to 23. The meeting was exceptionally well attended and was conceded by all to have been one of the most interesting and enjoyable held by the society. There were a number of papers that drew forth much heated discussion. The social functions, favored by ideal weather, afforded the members a splendid opportunity to renew old friendships and increase their acquaintanceship. Much of the success of the meeting is due to the able guidance of the committee of Philadelphia members.

Business Sessions of the Society

At the meeting of the board of directors, Thursday evening, various matters of importance were discussed. The place of meeting in the fall was definitely fixed as Lake Placid, N. Y., Sept. 28 to Oct. 1 inclusive. An invitation was read to meet in Buffalo in the spring of 1922, but no final action was taken. The board sanctioned the formation of a Division on Electrothermics which will include all those members interested in electric furnaces, electric steel, electric brass, etc., electrodes, refractories, regulators, heat-treating apparatus, etc. Acheson Smith is chairman of the new division. President Landis appointed a committee of three, William Blum, George B. Hogaboom and H. S. Lukens, to canvass the membership of the society and ascertain whether a division on electrodeposition would meet with the necessary support and encouragement. The division, as proposed, is to cover the subjects of electrolytic refining, electroplating, electrotyping and electro etching.

At the annual business meeting on Friday morning the following new officers were elected: President, Acheson Smith; vice-presidents, Charles F. Burgess, C. G. Schluederberg and E. L. Crosby; managers, Carl Hering, J. V. N. Dorr, F. A. J. FitzGerald; treasurer, P. G. Salom; secretary, Joseph W. Richards. The treasurer's report for the term 1920-21 showed total assets, \$13,100; total receipts, \$24,000, and total expenditures \$28,134, of which \$19,730 covered the publication of four volumes of the *Transactions*.

In the absence of Dr. Baekeland Mr. Hamilton, examiner of the U. S. Patent Office, reported briefly on the present status of the patent bills before Congress. He emphasized that the Patent Office was flooded with applications and that work was proceeding very slowly and inefficiently, due to lack of proper financial support and encouragement for the employees to remain in office. Mr. Hamilton also urged the members present to exert their influence in encouraging the teaching of electrochemistry in schools and colleges.

The publication committee's report was presented by Dr. Fink. It was decided to hold a session on Non-Ferrous Electrometallurgy and another session on Electrodeposition at the coming fall meeting of the society at Lake Placid. At the spring meeting, 1922, there will be a session devoted to Electric Furnace Cast Iron. For future meetings, Dr. C. W. Moore suggested a symposium on "Electromotive Force" and E. O. Benjamin suggested a symposium on the production and utilization of "Electrolytic Gases" such as hydrogen, oxygen and chlorine.

At the conclusion of the business meeting a number of amendments to the constitution were voted. According to one of these amendments a quorum of the society shall henceforth consist of fifty members instead of 10 per cent of the membership, now totaling 2,300. Another amendment authorizes the board to appoint an assistant secretary who shall relieve the secretary of all clerical work. A new section was added to the constitution providing for a nominating committee.

At the conclusion of the business meeting the retiring president, Dr. W. S. Landis, delivered a highly interesting and instructive address entitled "Our Inventory."

Presidential Address—Our Inventory

BY W. S. LANDIS

At long and irregular intervals it was the habit of the proprietor of the crossroads general store to walk slowly through his place of business, glance to the right and to the left, and up and down, and make mental notes on the status of his stocks. So long as this crude method of determining his inventory was satisfactory to himself he remained the country storekeeper or fell by the

wayside. If through accident he developed to the stage of actually "taking stock," he abandoned the country store, moved to the nearest town and opened up a larger and more elaborate, though frequently more specialized, place of business.

There is a wide difference between the primitive stock-taking of the crossroads merchant and the continuous inventory carried by our modern corporation, and we of the newer school are still theorizing as to the ways and means which keep some of the old timers in the field. At the same time when we look into our own branch of industrial activity, I think we will find its system of inventory is in much the same condition as that of the crossroads store. Are we carrying such a form of inventory as to enable the quick determination of the quantity and quality of stocks on our shelves? Is this stock suited to our markets? Will we be able to meet our competitors on their own terms? How much do we know of the future prospects of our business? Remember, I am speaking here of the industry as a whole and not of any specific branch or unit.

MAGNITUDE OF THE ELECTROCHEMICAL INDUSTRY

The industry with which we as members of this Society are associated—that one utilizing the chemical and thermic effects of the electric current—represents, on the North American continent, an invested capital of something over six hundred million dollars. As a matter of fact this may actually be upward of a billion dollars, but our antiquated crossroads system of keeping our inventory does not permit us any great degree of precise determination of such factors. The lesser figure does not include, so far as it has been possible to segregate the same, those portions of plants not exclusively a part of the electrochemical process, nor does it include generating stations where they are operated as separate corporations. The great difficulty, however, has been to determine where the line should be drawn in those industries which use the same equipment for products derived from electrochemical or electrothermic sources, and from other sources independent of the electric current. It is this indefiniteness that represents the difference between the six hundred million dollars and the billion dollars mentioned above.

The casting of a balance sheet of an industrial group the size of ours is a somewhat different task from merely keeping up the inventory of an individual unit making a part of the whole. We are dealing with factors here as fundamental items which are usually only considered from the unit standpoint as intangibles.

My attempt at compilation will fall far short of the desired completeness we all desire, but matters of this sort and in this place can always be passed on to one's successors.

LOCATION

Our first item of consideration is the value of the location we have chosen to establish our industry. It is not unusual to hear, for example, that Norway is the logical home of the electrochemical industry, or that Germany will stifle all future competition in our line. Are we to consider, on the basis of such broad and unsupported statements, that our choice of location has been an unfortunate one—that we are located on a side-street in a poor neighborhood—that America is a liability to us instead of an asset? Personally I have no time for such propaganda—I am not even disturbed by the fact that a prominent American corporation has

established a Norwegian branch factory. The mere fact that Norway seems to have an abundance of undeveloped water power will not make it the Mecca of the electrochemist, for it takes more than undeveloped water power to build up an industry such as ours, and when one considers that Norway possesses no local markets, must import every pound of coal and coke, is short of skilled labor and uncertain as to temperament of the little unskilled labor available, I am not ready to write off very much on our choice of location.

In appraising the value of location, one must consider many factors, for example: The liberal form of government under which we live for a time showed a decided tendency toward an unfortunate socialistic attitude to industry. This now appears to have been only an incident of the war and prospects ahead of us are that we shall soon be clear and free to develop in proper competitive and individualistic manner. Laws governing proper combinations for meeting foreign competition are becoming more constructive and helpful. Outside of England I do not believe a single European nation can today compare in as liberal prospective legislative helpfulness.

TRANSPORTATION

As to transportation, the war left us a great fleet of merchant ships capable of taking adequate care of our export business. Unfortunately operation of this fleet is handicapped by marine laws framed by prairie sailors. Some day our scheme of government may advance to that state of development where political expediency makes way for skill and experience in the proper planning of specialized activities. Improvement of inland navigation in many cases goes hand in hand with hydro-electric development, all of which will help to unload our railroad systems. The electrochemical industries should be the preferred customers of such inland water transportation systems because of their location.

Our railroad system is the best in the world, even in spite of the universal domestic criticism. Just ask any returning foreign traveler. But development is at a standstill, rates are impossible; in fact in this case "best in the world" really means everything is pretty poor. The railroads are in for a complete reorganization—new management, new policy, greater efficiency from fewer and better employees—and they had better start pretty soon and get it over with or industry will again be on their heels.

WATER POWER

The recent water-power legislation will certainly lead to several important new hydro-electric developments and the possible establishment of new electrochemical centers. When prices of construction materials and labor drop to a point when the fixed charges imposed on the power cost are not too burdensome, work will begin on the many long-delayed projects. Our industry is bound to profit through these undertakings.

FUEL

Someone has said that electricity in electrochemistry is merely an excuse for burning coal. When one looks over the fuel requirements of the heavier electrothermic industries, the statement is not a great exaggeration. Nowhere outside of the United States is there already developed the abundance of high-grade fuel that we have near our electrochemical centers. Continental

fuels are of inferior grade and higher in price. Even English coals are going to be expensive in the future. Of the materials for making electrodes, we have in plenty and of such quality that today our large carbons command first place throughout the world.

RAW MATERIALS

It is no doubt true there are a few raw materials used in this industry with which we are not abundantly supplied. During the war emergency special efforts were made to develop the production of these miscellaneous materials, and the efforts were crowned with some success. If a fraction of the great sums of money spent on war plants which were of absolutely no use whatever toward the winning of the war—and I am not including here many plants founded upon perfectly sound engineering judgment and certain of performance but not completed before the signing of the armistice—had been spent on the search and development of some of our less plentiful raw materials, I might have a different story to tell with respect to these less abundant materials.

I believe after due consideration of the few facts just stated that we can write our choice of location down on the asset side of our balance sheet and give it a very high value. On the other hand there is no doubt that we must place against this large asset a small liability for shortage of a few rare materials and a larger liability for the disorganized state of our transportation systems. But so far the assets greatly exceed the liabilities, which foreign propagandists will please note.

The chemical industry of this country is comparatively new. We did not possess the background of alchemists that Europe had, but we seem to be fast making them. Our schools of chemistry have only in the last few years taken on a semblance of Americanization, for most of our older teachers were educated abroad and equipped their laboratories almost exclusively with foreign apparatus. This has not been altogether satisfactory, for our industry is primarily an American one using American processes worked in American apparatus, and supervised by American engineers. Aluminum, carbide, graphite, metallic sodium and a host of other products are primarily of American origin. The caustic soda and chlorine industries use almost exclusively American cells. As a matter of fact I do not know of anything in the industry of any great importance that has been brought over from Europe and held to its original European form for any length of time, and I know of only one considerable development in Europe that seems not to

have been brought here at all. With these facts in mind, we must agree that the American engineer is superior to the European in all electrochemical and electrothermic development, in spite of his semi-European chemical training. It is our duty to impress these facts upon the direction of our schools of higher education and render all the assistance we can to Americanize their methods and equipment.

Our industry with six hundred million to one billion dollars of capital investment looks for a profit of from one hundred to two hundred million dollars annually to meet capital charges and provide for reasonable growth and development. This return must come from the direct efforts of those charged with the conduct of the business—the executives, superintendents, engineers, etc. In other words men largely technically

trained are responsible for the earning of this enormous sum of money, and the universities and technical schools must in turn supply these men. Looking at this from a "gross" standpoint, the electrochemical industries must return approximately five hundred million dollars per annum, largely via university products.

Only a few technical schools make direct attempts at turning out electrochemists. Some others merely provide auxiliary courses in electrochemistry, and a still larger number merely group the subject with physical chemistry. There are practically no schools capable of properly handling post-graduate students in electrochemistry, because they do not have the necessary equipment.

In our schools of civil engineering we give our men regular drafting equipment. They work with standard levels and transits, and do not use small-scale model

testing machines in their study of materials. In our schools of mechanical engineering we provide our men with regular boiler plants and operating steam engines, not models. The students are not forced to work with miniature automobiles or internal combustion engines in any laboratories with which I am familiar. Why, therefore, should we expect in the training of our electrochemists that they should do their work in the laboratory entirely with glass beakers or similar small-scale equipment?

Why should the only representative electric furnace with which they ever come in contact during undergraduate days be either a picture or a small model, or in a few particularly fortunate cases exist in some nearby industrial plant that is open to their general inspection? If we are going to really educate electrochemists, we must provide in the university as a part of the daily working equipment, not models, but actual

ACHESON SMITH

Newly Elected President of the American Electrochemical Society

industrial installations, and operate these before and with the student through the assistance of practical electrochemists, supplementary to the theoretical instruction and lecture work.

I very much doubt if the universities of this country have available and are spending \$100,000 per year for the direct teaching of electrochemistry. I do not know of a single school laboratory that has a thousand kilowatts available for electric furnace work, or more than a model plating or refining equipment. If the industry is going to expect the graduates of institutions operating under such handicaps to return to it a gross of some five hundred million dollars per year and a net of from one hundred to two hundred million dollars, it will have to do something for our educational institutions along electrochemical lines, otherwise the German threat may not be all propaganda.

This Society holds two meetings a year, and averages nearly a thousand pages of publications annually. Our system of keeping inventory does not permit us to determine just what net returns the industry obtains from the communications, meetings and other services rendered by the American Electrochemical Society. It is my opinion that it adds directly a good many thousand dollars per year toward the net of the corporations. I am certain that if we include the dues of members paid by the corporations, the corporations will not have contributed \$2,500 per year to the support of the Society, an extremely small percentage of the net return they derive from the existence of just such a body at this.

The Society is doing the best it can and to the extent of its available means to advance the interests of electrochemistry. With larger means it could do a great deal more. The officers of the Society believe that it would be unwise to attempt to raise additional funds by increase of dues. There is, therefore, only one way to obtain the greatly needed additional income which the Society could profitably use and that is through some working arrangement with industry whereby additional funds could be secured on something other than a charity basis. Since I am merely casting up an inventory which is presumed to be a record of facts and not of opinions, I merely wish to leave this idea with my successors with the hope that they can work something out of it.

LABOR

As to the ordinary labor in our plants, I am not prepared to say that it is of as high quality as might be found in other countries, but at the same time I will not class it lower. On the other hand, we use only a fraction of the quantity in this country that is used abroad. We use automatic devices much more freely. We build larger units and operate them at higher capacities. In consequence while our common labor may not be quite so steady and is not so cheap per man-hour, when we consider the quantity used I do not believe that labor places an extremely serious handicap on the development of the American industry.

There are many labor abuses which will have to be corrected. The demoralization incident to the war is already being eliminated and it will probably not be long until our labor cost will not be the determining factor in foreign competition.

Reviewing our item of personnel, I think we can list the engineering ability, inventiveness and efficiency of the American engineer and the American workman as

an asset of particularly high value. I cannot place the technical school and the Society on the other side of the balance sheet, because that would put them in the false light of being liabilities, when as a matter of fact we know they are not, and have been rendering wonderful service under existing handicaps, but at the same time I think we must all admit that they are not up to the standard we are desirous of setting for such institutions and that our first endeavor in rectifying this inventory should be directed to improving those two items.

I could continue in this manner to discuss many additional items, such as our research and technical organizations, periodicals, our prospective future developments, and a host of others; they all call for attention which time forbids my yielding. I am certain all will fall in with our assets.

CONCLUSIONS

Close scrutiny of our balance sheet shows our industry to be in excellent condition. Every such report I have ever seen of a going concern always has a liability side and we are no exception. General business conditions at this time are not good. Low exchange values of foreign coins, coupled with questionable economic practices in some of the European countries, are causes of temporary but immediate concern. Bad habits acquired by our legislative bodies during the war and not yet broken will trouble us for some time. The relationship of our schools and this Society to the industry can be improved. All must be properly weighed and considered.

On the other hand, the wonderful opportunities America affords for the development of our industry, the skill, activity and courage of our engineers, all against the historical background set up by Acheson, Castner, Cowles, Hall and a host of other early workers, can mean only the most successful future. Let us take full advantage of the opportunity.

Technical Sessions

There were three technical sessions, one on "Arc Welding and Electric Furnaces," another on "Electrolytic Products and Cells" and a third on "Corrosion." In addition to these there was a public address by Dr. R. B. Moore on "Helium." Brief accounts of the papers presented at the various sessions, together with the discussions, are given below. The Symposium on Corrosion is treated collectively in a separate article. Corrosion is a topic of ever-increasing importance and many of the authorities on the subject attended the symposium.

HELIUM AND OTHER RARE GASES

A most enjoyable and instructive lecture on his experience and research with the rare gases of the atmosphere was delivered before the members of the Society Thursday evening by Dr. R. B. Moore of the U. S. Bureau of Mines. With the aid of numerous lantern slides and practical demonstrations Dr. Moore sketched the history of the rare inert gases, referring to the work of Cavendish, Lord Rayleigh, Sir William Ramsay and others. He described the three important processes for separating helium from other gases: The Claude, the Linde and the Jefferies-Norton. The capacity of the new plant at Fort Worth, Tex., is 35,000 to 40,000 cu.ft. of helium per day. The lifting power of helium is 92 per cent of hydrogen. The cost of helium

by the Jefferies-Norton process is about \$30 per 1,000 cu.ft.

ARC WELDING AND ELECTRIC FURNACES

O. H. Escholz, research engineer of the Westinghouse Co., East Pittsburgh, presented a study of the Phenomena of Arc Welding. Vaporization and condensation of electrode material cannot account for all the metal transfer, since the energy input is insufficient to vaporize metal at the rate it is consumed. In fact 60 per cent of the energy is probably absorbed in liquefying 90 per cent of the wire electrode, 25 per cent in vaporizing the remainder, leaving 15 per cent for radiation losses. Expansion of gases occluded in the welding wire undoubtedly occurs, but this is not the cause of extensive transfer of metal, because "gassy" wires do not deposit at high rates; in fact quite the opposite. Escholz therefore holds that the electrode metal is transported when gravitational force exceeds the sum of surface tension and cohesion in a globule of liquid, or when physical contact is made with a wetted surface (plate metal liquefied by anode energy).

In the discussion of Mr. Escholz' paper C. J. Holslag, of Newark, did not believe that magnetic effects were very pronounced in arc welding. It was his experience that the metal passes from the electrode to the work as a vapor. The heat generated at any instant in a particle of metal at the tip of the electrode is transferred in the next instant to the work. This accounts for the high temperature of the work. Henry Hess, of Philadelphia, suggested that it would be interesting to determine the speed of metal deposition by the arc.

ELECTRIC FURNACES FOR NON-FERROUS METALS

H. W. Gillett of the U. S. Bureau of Mines gave the next paper, on "Electric Furnaces for Non-Ferrous Metals." This paper contains many details on the electric furnaces in operation in the United States melting non-ferrous metals. Makes and capacities are summarized in Table I, and the applicability of various types of furnaces to common alloys is noted in Table II.

Non-ferrous electrometallurgy has made wonderful

TABLE I. SUMMARY OF ELECTRIC FURNACES

strides within the last five years and the electric furnace has been firmly established in the brass and bronze industries. At the coming Lake Placid meeting a whole session will be devoted to the subject.

ELECTRODYNAMIC FORCES IN ELECTRIC FURNACES

Dr. Carl Hering of Philadelphia, in his paper on "The Electrodynamic Forces in Electric Furnaces," described in detail the various "effects" met with in the operation of electric furnaces. Conductors carrying large currents are surrounded by a magnetic field exerting a strong force perpendicular to the surface. If the conductor is a liquid—as in some channeled electric furnaces—the current and its accompanying radial compression may cause the conductor to part; the phenomenon has been long known as the pinch effect. A complementary force is the so-called "stretch" effect, which tends to lengthen a conductor and causes a liquid conductor to move along its axis or heap up on the outside of a turn. Furthermore, strong eddy currents are set up in a liquid conductor on the outside of a square corner; "corner" or "motor" effect. All these circuits tend to produce motion which sets up a counter e.m.f., an observation thought to have the generality of a law.

G. H. Clamer of the Ajax Metal Co. took exception to a number of the statements made by Dr. Hering. He referred to the early work of Schneider, president

TABLE II. APPLICABILITY OF VARIOUS TYPES OF ELECTRIC FURNACE TO VARIOUS ALLOYS

O.K. = Furnace metallurgically satisfactory for this alloy.
? = No data on hand.
O.K.? = Probably satisfactory, but no record of trial.
No = Furnace not satisfactory for this alloy.
¹ Temperatures probably rather high for good refractory life.

² Question of copper poisoning by fume from direct arc not yet settled.
³ Induction furnace on this alloy would require resistor tube of special design.
⁴ Lead too high for good life of usual lining of induction furnace.
⁵ Furnace causes loss of volatile metal from this alloy.

of the Creusot Steel Works, France, and to his furnace with a liquid resistor outside the bath. In the Ajax-Wyatt furnace the pinch effect is not the sole factor. Its successful operation is based upon a combination of the pinch effect and the motor effect. The motor effect is caused "by the repulsive action of two conductors carrying unlike currents, thus causing the particles of metal in the conductors to be repulsed as far away from each other as possible."

RECENT PROGRESS IN HIGH-FREQUENCY INDUCTIVE HEATING

"Recent Progress in High-Frequency Inductive Heating" was the title of Dr. E. F. Northrup's paper, a sequel to that presented before the Society in April, 1919. His new paper was received with great applause and very favorably commented upon. It will be published in full in a future issue. In discussing his own paper Dr. Northrup pointed out that so far only the "star" connection was found to be practical when using this style of furnace on a commercial three-phase circuit; the "delta" connection does not work properly. He recently melted a fairly large quantity of a very high melting alloy composed of tungsten, osmium and a little nickel; he has also melted a sample of pure tungsten in his furnace. Dr. Northrup described in detail the building up of the inner lining of his carbon or graphite crucible. This lining will withstand a temperature of 2,000 deg. C. and is practically impervious to gases at this temperature.

Dr. Northrup said that he had found lampblack to be the best heat insulator at high temperatures. Graphitization of carbon is carried out so readily in the high-frequency furnaces it is probable that this may become one of the main uses for the furnaces. By imbedding a compressed piece of carbon in lampblack the graphitization can be carried out very easily. Similarly, a pure rod of cobalt can be produced by introducing into the Northrup furnace a compressed rod of cobalt powder packed into very finely divided and loosely packed cobalt powder. The metal rod so made will be practically free from carbon.

Mr. FitzGerald of Niagara Falls referred to some of his experiments years ago on the graphitization of carbon, stating that he had encountered all kinds of difficulties in keeping large pieces of carbon from cracking. Would this difficulty be easily surmounted when graphitizing in the Northrup furnace? Dr. Fink pointed out that the success of a crucible lining such as Dr. Northrup described was largely a matter of grading the layers so as to pass, step by step, from a low coefficient of expansion to a higher one. This same principle is successfully applied in fusing special low-expansion glass to ordinary high-expansion glass. L. E. Saunders of Worcester suggested that Dr. Northrup try magnesium oxide linings, which also can be made very impervious.

REGULATION OF ELECTRIC STEEL ARC FURNACES USING MOVABLE ELECTRODES

W. G. Mylius of the Westinghouse Co. then presented his paper on "The Regulation of Electric Steel Arc Furnaces Using Movable Electrodes," describing a new regulator designed to give rapid and close regulation of heavy electrodes without "hunting." Assume a cold furnace. When the main circuit breaker is closed voltage coil *V* (see illustration) is energized, closing contact 3 and operating electrode motor continuously

and at full speed until it comes in contact with the bath, when *V* will be de-energized instantly, opening the motor circuit. As no alternating current can exist in any electrode until two or more are in contact with the bath, current coil *A* will not be energized until that time, when contact 4 will be closed, causing the motor to raise the electrode and drawing the arc. When the pull of coil *V* builds up to that of coil *A*, the lever becomes horizontal and the motor stops. Current can be adjusted within a 20 per cent range by rheostat *C*.

Auxiliary contacts 5 and 6 respectively operate simultaneously with the "lower" or "raise" contactors on the motor control circuit and shunt part of coils *A* and *V*. When the induced change in pull by change in current and change in turns is sufficient to restore

the lever to horizontal the motor will stop. A vibrating condition exists between control element and contactor whenever the current per phase is less than 15 per cent on either side of normal value, and the motors are subject to a series of impulses, the average length of which, being a function of the amount of furnace current, deviates at any instant. This also allows

SCHEMATIC DIAGRAM OF CONTROL ELEMENT CIRCUIT

the motor to operate at high speed until the current has been brought to within 15 per cent of normal, when the speed is gradually reduced to zero, thus preventing "overshooting" and allowing automatic regulation on a cold charge. It is also impossible for an electrode to run down into the bath when current fails. One electrode can be withdrawn without disturbing automatic equilibrium in the two others. If voltage drops to zero, control levers balance and all motors stop.

A lively discussion followed. Mr. Bennett inquired about the power factor of the new regulator. According to his experience there was considerable lag in the reversing switches and hunting or overshooting is hard to eliminate. But even at an electrode feed of 24 in. per minute he has obtained regulation within ± 2 per cent. Mr. Kellerher of Canada has found the Thury regulator to operate within ± 1.5 per cent under normal conditions. E. L. Crosby, Detroit, pointed out that as far as the central station was concerned the interest in the regulator was not confined to "normal conditions." According to his experience ± 10 per cent was nearer correct. Mr. Seede of the General Electric Co. said that up to 1913 or 1914 the step-by-step regulator had the field for itself. But in many a case it did not seem altogether satisfactory, and accordingly the continuous movement regulator was developed, which proved in many respects an improvement over the Thury. President Landis found that the mechanical feature of the regulating equipment and the quick response of the motors was most important in carbide furnaces with electrodes weighing 10 tons each. Mr. Seede reported that even with 10-ton electrodes the regulation could be kept within $\pm \frac{1}{2}$ per cent, using the continuous movement regulator.

A NEW PHOTO-ELECTRIC CELL

B. S. Cushman of Auburn, N. Y., presented a highly interesting paper by T. W. Case on a photo-electric effect in audion bulbs of the oxide coated filament type.

CHART SHOWING SENSITIVITY OF STRONTIUM CELLS TO LIGHT

Mr. Case reported that he has been able continuously to record daylight intensity for the past several months. The photo-electric effect on barium and strontium filaments in audion bulbs furnishes a current of 100 to 150 micro-amperes which actuates an automatic recorder.

Mr. Cushman showed two strontium cells and reproduced on the screen a number of daylight records which had been automatically registered by a Leeds & Northrup potentiometer. One of the cells had almost the same sensitivity as that of the human eye to light. The barium cells are sensitive to the longer rays, the strontium cells to the shorter rays. The sensitivity of the latter is shown in the illustration. In the discussion Dr. Richards suggested that the addition of a small amount of Sr to the Ba as a stabilizer might be similar in its effect to the addition of Ce to Th in the Welsbach mantle.

ELECTROLYTIC PRODUCTS AND CELLS

The apparent irreversibility of the calomel electrode was investigated by A. W. Laubengayer of Cornell University. Some years ago Paschen had pointed out that a mercury anode polarizes much more strongly in hydrochloric acid than in sulphuric. Mr. Laubengayer finds that the apparent irreversibility of the electrode is not real, but is due to the formation on the surface of the mercury anode of a strongly adsorbed film of mercurous chloride, which offers a high resistance to the passage of the current. Why mercurous chloride should behave so differently from mercurous sulphate could not be established. The paper was briefly discussed by Dr. Fink, who suggested a microscopic study of the films.

ELECTROCHEMICAL ASPECTS OF PHOTOGRAPHIC DEVELOPMENT

"The Electrochemical Aspects of Photographic Development" was the title of the next paper, by Dr. S. E. Sheppard of the Eastman Kodak Co. In it he discussed previous work and added information being developed at the research laboratory of the Eastman Kodak Co. He discussed the physical chemistry of the development reactions, and pointed out the present unsatisfactory value of the measurements by electrical methods, which are entirely relative to the particular experimental conditions.

ELECTROLYTIC MANUFACTURE OF PARAMINOPHENOL

Another contribution by the Eastman research laboratories was presented by A. S. McDaniel. It dealt

with a war-emergency investigation on the electrolytic manufacture of paraminophenol. The research was carried out jointly by Messrs. McDaniel, Schneider and Ballard.

ELECTROLYTIC NICKEL

Two papers on electrolytic nickel gave rise to a very animated and lengthy discussion in which both practical and theoretically inclined members participated. The first, by William Blum, electrochemist of the Bureau of Standards, was on "The Use of Fluorides in Solutions for Nickel Deposition."

Charles P. Madsen was the author of the second paper, "Ductile Electrolytic Nickel." These two papers will be published in full in a subsequent issue.

A NEW HIGH-CAPACITY STORAGE BATTERY

C. W. Hazelett gave a description of a thin plate storage battery recently designed by him. The performance of this battery based on the amount of lead and active material varies from 50 to 200 per cent above that of the standard types. The higher percentages prevail at exceedingly high rates and at very low temperatures. It is machine made and a large decrease in cost of production has resulted. It is not subject to the mechanical defects and the variability experienced with present standard types.

It has been found practical to ship charged elements, wrapped in paper, to service stations for rebuilding batteries where the container is in good condition. This is due to the fact that the separators which hold the electrolyte like a lamp wick do not allow the plates to dry out any more than when immersed in electrolyte. By this system a complete battery may be rebuilt in less than an hour at approximately one-half the regular cost. This unusual principle is made use of where a non-spill battery is required by simply pouring out the excess acid when the battery is in use and replacing it while recharging. There is practically no decrease in capacity when this is done.

Since the life of a battery is practically always destroyed by buckling plates and short-circuiting or by the washing-off of the active material and since neither of these conditions is possible with the Hazelett storage battery, very long life would be expected. Conservatively speaking, their life is averaging from two to three times that of the standard types.

Walter E. Holland, of the Philadelphia Storage Battery Co., referring to Hazelett's battery, reported upon comparative tests carried out at his research laboratory. He felt that a number of the claims made by Mr. Hazelett—e.g., those in regard to voltage performance and capacity—were somewhat exaggerated.

MARSH CHLORINE-CAUSTIC SODA CELL

The final paper on the program was entitled "The Marsh Electrolytic Cell Batteries for Chlorine, Caustic Soda and Hydrogen," by C. W. Marsh.

Mr. Marsh gave a brief description of a high-capacity cell for electrolysis of brine, containing graphite anodes, corrugated sheet steel cathodes, with asbestos paper diaphragms clamped tightly to the edges of the cathodes. Arrangements are made for collecting both chlorine and hydrogen. Single cells are made to take up to 2,500 amp. The ampere efficiencies over long periods amount to 90 per cent; the power efficiencies 50 to 65 per cent.

The cell consists of three parts: a structural top with downward extended ends, anodes suspended from the

top, and a cathode clamped to the top and ends, forming the electrolyte compartment. The cell is supported from the top in a box or on insulated beams or suspended from the top through insulated bolts inserted in the top. A hoist operating from an overhead trolley beam or any similar overhead device is used for assembling the cell and to raise and lower the cell into position.

The structural top is like an inverted trough with downward extended narrow ends. The material may be stoneware, re-inforced concrete or other suitable material. Openings are provided in the top for brine inlet and automatic brine control device, brine level indicator, brine gage glass, chlorine outlet, cleaning holes and openings through which extend the top of the anodes.

The graphite anode consists of four, six, ten or any reasonable number of 1.75-in. (4.4-cm.) diameter graphite rods 24 in. (60 cm.) long arranged one above the other with spaces between and pinned to a rectangular section of graphite acting both as a support and a leading-in post. Pairs of these anodes are suspended from the top through clamps on the upper ends of the graphite posts.

The cathode consists of perforated sheet steel horizontally corrugated to conform to the surface of the horizontal graphite rods. The asbestos paper diaphragms are laid on the cathodes conforming to corrugations. The cathode is then clamped along the bottom edges of the top and against the ends with the diaphragm acting as a gasket. The cathode and the ends and top thus form the electrolyte compartment. The chlorine gas collects in the top above the brine. The caustic liquor forms on the cathode and is collected in the supporting box or by other trough-like receivers. The hydrogen gas may be recovered for use by confining the cathode in an inclosure, if the cell is suspended, or within the supporting box. The connections for electric

current and for other purposes are made in the usual way. Connections are made along the top of the cell.

Social Features of the Meeting

The afternoons of Thursday and Friday were given over to sports and recreation. The golf tournament attracted a large number of enthusiasts. The course of the Sea View Golf Club was in exceptionally fine condition and the weather was ideal. Through the courtesy of Frank Hodson the members enjoyed the hospitality of the club, and so many were the attractions and inducements of the club that a goodly number of the electrochemists forgot entirely about the technical sessions "the morning after." In order to make the golf tournament doubly interesting the committee, with Arthur E. Gibbs as chairman, had arranged for a large number of attractive and practical prizes, generously contributed by the Westinghouse Co., Stellite Co. and Monel Co. The prizes were awarded on Friday evening at a gathering of the entire Society in the large auditorium of the Chalfonte. The occasion was a most impressive one. L. E. Saunders made the presentations with appropriate comments on the skill and veracity of the individual contestants. The first prize went to John A. Seede, who, due to his characteristic "continuously regulated" strokes, netted the lowest score. Then there were second, third and fourth prizes. Also prizes for special distinction: C. G. Schluederberg received a prize for covering the largest area of the course; H. C. Parmelee received a very fitting little prize, a pocket adding machine. Mr. Parmelee's distinction was the largest number of strokes. When asked for his score, the committee had mistaken his score for his telephone number. As to the "indoor sports," first prize in billiards went to Dr. J. W. Richards.

For Symposium on Corrosion of Metals and Alloys see page 841 of this issue.

Properties of Various Metals and Alloys

Some of the important properties of various metals and alloys have been summarized in the attached table by R. W. Woodward of the Metallurgy Division, Bureau of Standards. These values are typical, but should not

be used for design purposes as of precise significance, especially if details of the special alloy in question are available. However, they form a most convenient reference table for data not commonly summarized, and are suitable for nearly all estimates.

Rochester Meeting, American Chemical Society

Report of the Sixty-first Meeting April 25-29, 1921—Council Meeting—Addresses at the General Meeting—Papers Presented at the Industrial and Engineering Chemistry, Dye, Rubber and Physical and Inorganic Chemistry Divisions, and at the Cellulose and Petroleum Sections

THE sixty-first meeting of the American Chemical Society was held at Rochester during the week beginning Monday, April 25. There were about 1,400 registrants, although the attendance was probably larger than this.

In view of the constantly growing burden of expense which the Society's meetings impose on their hosts, it was resolved at the previous meeting that greater simplicity of entertainment should be observed. To this general rule the Rochester Section conformed, but it made up for luxuries by perfect arrangements and order. Everyone was looked after, and every requirement was met without delay or inconvenience. It was a good meeting.

The Council Meeting

The Council meeting was called to order at 4:05 p.m. at the Rochester Club, President Edgar F. Smith in the chair.

Memorial resolutions were adopted in regard to the deaths of Dr. Albert C. Hale, formerly secretary of the Society, and Dr. I. D. Hines, for many years a member of the Council. Dr. George F. Rosengarten was re-elected to membership on the committee on national policy, succeeding himself. An invitation was presented from the Alabama Section to hold the spring meeting of 1922 at Birmingham, which was accepted.

Drs. Charles F. Chandler and William H. Nichols were elected to honorary membership. Under requirement of the constitution the names were acted on again by the members of the Society at its general meeting.

It was resolved that the Council express to the directors the hope that they absolve the printer of the Society's periodicals from any forfeit if he fails to deliver the journals regularly during the threatened strike of the printing trades for a 44-hour week. The conclusion was reached only after the increase in the cost of the periodicals which would follow the 44-hour week demanded in the printing trades was considered, and after a comparison was made of the rates of pay to journeymen before the war, now, and under the demanded advance. It was not from jealousy that the instructor in chemistry who receives less was unwilling to grant this request to his brother the compositor who receives more, but rather because he can't pay any more for his journals the while he must have them.

The proposal for a new section of the Society to be known as the Arkansas Section was adopted.

The appeal to Congress passed at the general meeting to safeguard the dye industry was passed by the Council.

It was determined that in future, if reports of committees are presented between meetings of the Council, these may be accepted and adopted by the advisory committee in the place of such action by the Council itself. This step was taken because sometimes it is necessary that preliminary reports be acted on to provide for further progress.

The committee on metric system offered resolutions

urging chemists and manufacturers to use metric units in specifications, and it was resolved that authors be requested to use them in their papers and that the editors request them to do so.

Dr. Charles Baskerville reported for the committee appointed to meet the American Mining Congress. The purpose of this was to conserve the mineral resources of the United States, and progress was noted. On behalf of the Holmes memorial committee he did likewise. The report on occupational diseases in the chemical trades was an illuminating discourse even in the abridged form in which it was presented. Some of its features will be discussed on another occasion in this journal.

The advisory committee presented for action a resolution recommending to the Commissioner of Patents that a trained chemist be appointed as chief examiner. This was carried, as was also a resolution that the secretary of each division be authorized to demand the submission of any paper offered for presentation at any general meeting, and that the chairman and secretary of each division have the power to decline any such paper, if, in their judgment, it is unavailable.

The number of members at the end of 1920 was 15,582.

Dr. Herty reported encouraging progress in regard to the proposed Institute of Chemo-Medical Research which was formerly referred to as the Institute of Drug Research. The committee has lately been in conference with the Chemical Foundation. A very favorable report was also received from the committee appointed to co-operate with the Chemical Warfare Service. A meeting lately held at Edgewood Arsenal shows that this immensely important property of the U. S. War Department is now being conserved and held ready against the time of need for it. In the light of the report a resolution was adopted complimentary to Brigadier General A. A. Fries and his associates for their splendid work in this connection.

A number of other committees reported, and in conclusion the Council declared itself in favor of the principles contained in the Nolan bill, which died in Congress, and opposed to the so-called Federal Trade Commission rider, which provided for the disposal by the Federal Trade Commission of patents taken out by Government employees.

During a recess the committees were the guests of the Rochester Section at dinner at the Rochester Club.

The General Meeting

The General Meeting was called to order at the Chamber of Commerce by Frank H. Lovejoy, chairman of the Rochester Section, who introduced J. Ernest Woodland, chairman of the executive committee, and Mr. Woodland made an address of welcome. He then introduced J. Bernard Haggerty, secretary to Mayor Edgerton, who gave the freedom of the city to everybody there. Next E. J. Miner, president of the

Pfaudler Co. of Rochester, after a felicitous introduction, made an earnest appeal for the encouragement of research. He deplored the tendency, frequently observed of late, to discontinue efforts in this direction because of hard times. He declared that intelligent research is not an expense, but rather an investment in insurance for the future. He indicated also a danger that scientific men, instead of addressing themselves too much to theory, are likely to become too utilitarian, and thus, by neglect of pure science, to render themselves unfit to meet with clear vision the greater problems that come before them. He made an earnest plea to magnify the importance of pure science, for in the men of science of today rests the hope for the future. It was an address that might well be printed and used as a tract to circulate among the business men of the country.

President Smith then took the chair, and responded on behalf of the Society to the words of welcome in his own delightful and engaging manner. The act of the Council was confirmed by the unanimous election of Drs. Charles F. Chandler and William H. Nichols to honorary membership.

Prof. Bingham of Lafayette College in a short address made a plea for the practice of dealing and trading in units of the metric system. Much more can be done in favor of bringing it into use by acting than by talking. He urged that wherever and whenever possible supplies and materials be bought in metric units.

Dr. Raymond F. Bacon of the Mellon Institute in a short address urged upon members to bear in mind how in 1914 many industries were closed down for lack of a few pounds of some needed product, and advised that in most of the forty-two legislatures now in session there are bills pending designed to enforce prohibition of alcohol as a beverage that include provisions which, if passed, will do no less than wipe out several legitimate and important industries. These are in no wise related to the drink evil. Many of the proposed statutes are drawn with the best intentions, but their provisions are fraught with serious danger. The Volstead act was designed, according to its caption, to provide for the prohibition of alcoholic beverages and to promote the chemical and industrial uses of alcohol, but the latter feature is being wholly forgotten in the legislation which threatens.

Captain G. B. Hide made an appeal for the Near East relief, and H. C. Howe announced that the fourth table of chemical and physical constants will be out by July.

SENATOR WADSWORTH FOR CHEMICAL PREPAREDNESS

Senator James W. Wadsworth, Jr., made no pretensions to chemical scholarship, but said that in the Congress of the United States he was far from being alone in the lack of it. He has only lately recognized the utter dependence of industry upon chemistry, and he has been made alive to the fact that if this science does not go forward with us we cannot progress as a nation. He would not undertake to instruct the audience before him in the relation of their own profession to national defense, but he had lately spent a day at Edgewood Arsenal, and wished that others might go there and see what it means to the people of the United States and to future generations. It is of staggering size. The people of this country, regardless of their politics or their opinions as to foreign or domestic affairs, should count themselves fortunate in having this great plant for their protection, held

in readiness and administered by so able and competent an authority as General Fries.

He had participated in considerable discussion in relation to the Chemical Warfare Service, more particularly in the Committee on Military Affairs, and this discussion had at times been rather lively.

The head of the department himself and the Chief of Staff had contended against a separate Chemical Warfare Service, and had wanted it merged, or, rather, submerged, in the Engineers Corps. The members of the committee had a very slight understanding of the subject, but when they learned that 30 per cent of the casualties were due to gas, they had the wit to see that the service was not negligible, and legislation to keep it as an integral part of the army was finally enacted. In its last session Congress also appropriated money to make at Edgewood 120,000 masks and 120,000 extra canisters, which are the best masks that have been made anywhere, although even they do not protect against all known gases. He believes, however, that if we are compelled to go to war again, and the enemy uses gas, we shall have made good provision against it, and not be utterly unprotected in that respect as we were before. He believed it safe to say that Congress will not permit this service to perish.

There are, he said, conflicting views current as to the proper size for the United States regular army. Personally he does not favor a standing army that is too large, but rather believes in the proper training of citizens who in case of war have to do most of the fighting after all. But it is possible to make the regular army, which must serve as a nucleus in time of war, too small. With an army of 280,000 men, which is the maximum figure considered, the number of officers in the C.W.S. will be 100 out of a total of 17,800, and 1,200 enlisted men out of 280,000. But if the total number be reduced in the measure proposed by some earnest legislators, the enlisted men in the C.W.S. will be reduced to four officers and 400 enlisted men. This would be almost fatally inadequate.

Another point of information that was being learned is that high explosives depend on nitrates, and that if we do not produce them by chemical means we must send 10,000 miles away for them. He had never read in history of a people able to defend themselves unless they were self-reliant and independent. Now the best measure for national defense is that the means for defense be made by the people themselves. A government alone cannot provide for it in days of peace. Such preparation must be included in the peaceful occupations of the people. No government is competent enough or pure enough to do this thing of itself. For this reason he has opposed proposals to launch the United States Government in great industrial enterprises whereby it would invade the domains of business to prepare itself against the day of war. He repeated that since the people must fight the wars it is they who should prepare for them—and they should make nitrates as a legitimate business industry.

He would like to think that war will never overtake us again, but he can't be sure; and if we are not sure we are not warranted in neglect. In conclusion he rejoiced that a great organization like this, which builds for the future, gives its thoughtful consideration to the security of the country, and he looked upon it as a happy augury that if, in future, danger again threatens us, we shall have such a large body of skilled men on whom we can call.

ROCHESTER MEETING OF THE AMERICAN CHEMICAL SOCIETY

April 26-29

HANS T. CLARKE
VICE-CHAIRMAN

FRANK W. LOVEJOY
HONORARY CHAIRMAN

J. ERNEST WOODLAND
CHAIRMAN

ERLE M. BILLINGS
SECRETARY TREASURER

CHARLES F. CHANDLER

GILBERT N. LEWIS

HARRY L. B. GRAY
HOTEL COMMITTEE

FLORUS R. BAXTER
EXECUTIVE COMMITTEE

BENJAMIN V. BUSH
PUBLICITY COMM.

NICHOLAS LONGWORTH

EDGAR FAHS SMITH
PRESIDENT AMERICAN CHEMICAL SOCIETY

JAMES W. WADSWORTH

HARRY A. CARPENTER
CHAIRMAN REGISTRATION

IRVING LANGMUIR

C. E. K. MEES

HERBERT EISENHART
FINANCE COMMITTEE

CHARLES F. HUTCHISON
CHAIRMAN ENTERTAINMENT COMM.

CHAS. W. MARKUS
TRANSPORTATION

O. I. CHORMAN
ENTERTAINMENT COMMITTEE

ROBERT E. WILSON

RAYMOND F. BACON

WILDER D. BANCROFT

IVAR N. HULTMAN
COLLEGE & FRATERNITY DINNER COMM.

President Smith asked all to rise, and while the audience was standing, he expressed in a few eloquent words the sincere thanks of the Society to Senator Wadsworth for his splendid message.

CONGRESSMAN LONGWORTH ON TARIFF SCHEDULES

Congressman Nicholas Longworth followed. He said he had lately called at the most distinguished residence in the country, and that its occupant, who is the most powerful man in the country at this time, had said to him: "I hear you are going to address the American Chemical Society. That is good; but what the chemists of America most need is not talk, but protection."

The speaker said he was now chairman of that subcommittee of Congress which is framing the chemical schedule, and he admitted that it was a difficult job. Nobody can tell the cost of products, either here or abroad. It is a great field of guess-work. Therefore it is idle to pretend to follow the old slogan and declare that a proposed tariff bill will equalize the difference in costs, if they can't find out what these are! The market prices are by no means trustworthy guides, because of fluctuations. Even well-known chemicals have varied in price in thousands of per cent. One product widely used has had a range in the last few years of from 10c. to \$4 a pound. As far as possible, he hopes that we may go back to specific duties. But even these are often unreliable and a specific duty that might be a proper one today might, in some cases, be wholly out of proportion three or four months hence. On the other hand, as soon as we consider ad valorem duties we face the problem of foreign exchange, and that is another source of trouble. The only way to meet the situation is to have a valuation of foreign imports based on the wholesale values of the same products in this country, when it becomes necessary to fix an ad valorem duty.

Another great difficulty is that we have changed from a debtor to a creditor nation. How then can Europe pay its debt to us if we bar Europe from our markets? Again, how can we meet the low labor costs that prevail, for instance, in Japan?

The speaker believed that the true solution consists in maintaining a bargaining counter, and in having three rates of duty to apply:

1. As a regular rate.
2. A maximum rate to those who do not treat us as favorably as they do other countries.
3. A minimum rate to be applied only by order of the President and to be used in exchange; as, for instance, to silks from France against outgoing chemicals from the United States to France.

There is one class of merchandise for which no rate of duty even to a thousand per cent will suffice, and that is coal-tar dyes and other coal-tar products. We must not only put duties on some, but keep others out altogether. In the bill he introduced into the last Congress he proposed a licensing system, but the plan met the objection that Americans do not like to apply for licenses to carry on their business. What he hopes to bring about will be to divide dyes listed by the Tariff Commission into three groups, viz.:

1. Those that are not imported at all because they are made here in abundance and sold at reasonable prices.
2. Those occasionally importable because they are not made here in sufficient quantity to care for the industries that need them.

3. Those that are not made here at all and which may be imported freely.

Mr. Longworth is convinced that Germany is awaiting the day when she may flood this country with coal-tar products in such a manner as to kill the domestic industry. The German factories are running full time; they have not been injured, and their labor and chemical forces have not been called on to fight in the army. If we want to save this industry for the United States, with all that it means, we must put a flat embargo upon certain German products, and he believes that this time it will be done.

Another difficult matter is that the bill will hardly be ready for the President to sign after its passage through both houses before November or December, whereas the War Trade Board goes out of existence by July 1, or possibly sooner. To make provision against such dumping of German goods into this country some unusual legislative steps will have to be taken, but he has hopes of this also. In short, Mr. Longworth believes that the members of both houses have finally come to realize that our preparedness for defense lies in our chemical industries.

In conclusion he repeated Senator Wadsworth's observation in regard to the immense advantages to the country in having the American Chemical Society to which it can turn when under threat of war.

President Smith again asked the audience to rise and in the name of the Society he thanked Representative Longworth for his happy and heartening address.

MEASUREMENT OF COLOR

Dr. E. K. Mees of Rochester gave an illustrated talk on "The Measurement of Color." The development of the colorimeter has proved that the subject is of interest to manufacturers as well as to physicists and chemists; the range of industries calling for color measurement including makers of soaps and makers of soups. We can measure the stimulus that produces the sensation of color, and we can measure the sensation itself. Thus the stimulus is found in the cause of the sodium flame, whereas the sensation is produced directly by a dandelion. While to us the color of both is alike, they are wholly different in the spectrum. To examine the stimulus we must use analytical methods, while to measure the sensation our methods must be synthetic.

BLUE EYES AND BLUE FEATHERS

Prof. Wilder D. Bancroft, in talking on "Blue Eyes and Blue Feathers," said there is no pigment in blue eyes, but that the sensation of blue is explained by the presence of a thin layer of minute particles between which the long red waves pass without touching them, whereas the short blue waves are sure to strike them so as to be deflected, or at all events so scattered that they produce the sensation of blue. Gray, green and brown eyes are due to more of these particles against which the impact of longer waves makes itself manifest. He followed with an explanation of the color of blue feathers.

The chameleon and the flounder produce different effects of color by the arrangement of particles in their skins. Slides were shown of a patient flounder which took protective coloring from a large number of bottoms over which it was placed, and it showed amazing attempts at conformity to the surfaces beneath it. Over sand and over granite rock and over a considerable number of various bottoms it became almost

invisible, whereas when such an unusual surface as a chessboard or other regular figured bottom was provided, the poor fish did its best, but couldn't quite meet the requirement. A test that seemed unfair was to place it so that the head was over a black surface, and the rest of it over white. The fish saw only the black, and turned as dark as it could all over. It turned as near white as it could with the conditions reversed. The protective coloring is due to a volitional change in the particles under the surface of the skin, and copies more or less closely what the fish or chameleon sees. It is not due to pigmentation of the skin.

SURFACE FILMS AS PLASTIC SOLIDS

Robert E. Wilson, director of the Research Laboratory of Applied Chemistry, Massachusetts Institute of Technology, gave a general address on the structure of surface films. By a variety of new and ingenious methods it was demonstrated that the stability of most, if not all, stable bubbles is due, not to the mere lowering of surface tension, but to the formation of *plastic solid*, rather than *liquid*, films at the liquid-gas interface. These films are probably gel-like in structure, and owe their formation to the concentration of the bubble-forming material (such as soap) at the interface. The same essential conclusions were also shown to apply to the interfacial films between oil and water, which are formed by the ordinary emulsifying agents. Here again the presence of a plastic solid, rather than a liquid film, is the main factor in preventing coalescence of the drops. Plastic solid films also appear to play an important part in lubrication.

Prof. Wilson also showed that the presence of these solid films, at all except the lowest concentrations of materials such as sodium stearate and saponin, caused erroneously high results in the ordinary (Du Nuoy or drop weight) methods of measuring surface tension between solutions and air or oil, etc. The measurements in such cases really represent the sum of the surface tension plus the frictional resistance to rupturing the film. While it has not yet been found possible definitely to separate the two effects, they are at least of the same order of magnitude, and in many cases the frictional forces are larger than the surface tension forces, as witnessed by the grotesque deformed and pointed, and yet stable, drops, of which pictures were shown.

Indeed, the results may account for the hitherto unexplained fact that certain concentrated soap solutions will spontaneously emulsify oil, which would appear to indicate a *negative* interfacial surface tension, and yet oil dropped into the solution gives a reasonably definite drop weight which calculates over to *positive* value for the interfacial surface tension.

RELATION BETWEEN THE STABILITY AND THE STRUCTURE OF MOLECULES

Irving Langmuir amplified his previous presentations of the octet theory by showing the part played by electrons held in common between the positive fields of two atomic nuclei forming a molecule. The fundamental hypothesis states that stability is attained when the negative shell has its full quota of electrons as based on the structure of the inert helium series. An outer shell is not stable until it contains eight electrons; thus a stable molecule differs from the inert elements mainly in having more than one positive nucleus and holding one or more electrons in common. Double bonds exist

where two electrons are held in common by two nuclei and triple bonds exist where three are shared.

IONIZATION OF ELECTROLYTES

The activity of the ions or ionic strength of an electrolyte forms the basis of theoretical work with solutions. Prof. Gilbert N. Lewis has recently calculated tables from laboratory determinations which will form a very valuable addition to the present store of constants. It is predicted that mixed salt concentrations at saturation can be calculated and of course all work on electrolysis will be greatly benefited. The paper will be published in the current issue of the *Journal of the American Chemical Society*.

The Chamber of Commerce Luncheon

At the luncheon in the Chamber of Commerce there were over 1,000 present, and Dr. Arthur D. Little of Boston gave a popular talk. Business men, he said, deal in dollars. They go out after them and they have accountants to keep record of them, and they discuss them constantly. But dollars are only symbols of things, while things are materials and labor; and labor creates value only as it works on things. Now the nature and control of materials is the province of chemistry. Therefore chemistry is a partner in the manufacturer's business; a closer partner than the Federal Reserve Bank or the labor union. We have lawyers to look after man-made laws, but chemistry deals with its own laws, and a chemist is a counselor of chemical laws. Men who have to do with materials need chemical service, and since we have but one chemist to every 7,000 of our population, it is time that live men began to look around for good ones. One ounce of whiskey in 55 gal. of water makes a dilute drink, and that is the ratio of our mixture of chemists to people in this country; of men who study the ways of materials.

He cited a great number of instances in which the chemist had saved situations and added to the wealth of the nation, and explained in an illuminating manner the chemical foundation of production. He showed it should be the controlling consideration in regard to raw materials, how it finds suitable substitutes for materials needed that are too costly or too rare, and how it finds new outlets for products. He explained the value of scientific control of production, as well as how the chemist finds new uses for existing plants. The audit and sheet balance is a record of past performances. The research laboratory provides for and aids in future performances.

Petroleum Section

The question of organizing a Petroleum Section of the American Chemical Society was first taken up and discussed seriously in February of this year; the approval of the national officers was obtained early in March and the work of enrolling members and preparing a program was begun at once. Encouraging comment was received and about fifty persons indicated their intention of joining the Section; but the real prospect of success could not be judged until the test of holding a meeting had been applied. However, at no time after Wednesday morning, April 27, when the Section first met, was the fate of the project in any doubt.

In the field of petroleum so much of the research work and the information available are in the hands of the representatives of the industry that their support and co-operation are absolutely essential to success. That

such support and co-operation were being given was indicated by the presence of the chief chemists and technical directors of many large oil companies, a number of whom had traveled long distances to be present. These and an adequate representation from the universities and research institutions filled to overflowing the small room first assigned for the meetings of the section and two movings were necessary before adequate quarters were found.

The time of the Section was divided between the business of organization and a short but very interesting program of papers. In arranging for the meeting, the Council, through the national officers, had appointed Dr. T. G. Delbridge, of Philadelphia, chairman and Dr. W. A. Gruse, of Pittsburgh, secretary. The organization, as voted by the meeting, provides in addition for a vice-chairman and an executive committee of five members, who are to conduct the business of the Section; the payments of dues were decided upon, and in order to facilitate and stimulate intelligent discussion of papers it was voted to circulate, prior to a meeting, abstracts of all papers to be presented; the circulation of written discussion was also considered. Standing committees on papers and on membership were provided for.

PETROLEUM HYDROCARBONS THAT CANNOT BE DISTILLED

The first paper on the program which followed the preliminary organization was one by Dr. Charles F. Mabery, of the Case School of Applied Science, Cleveland, by seniority and by merit dean of investigators in the field of petroleum chemistry in this country. Dr. Mabery's paper was on "A Method for the Separation of Petroleum Hydrocarbons That Cannot Be Distilled." The principle employed was that of fractional solubility in hot ether-alcohol; by repeated treatments the author has separated individual hydrocarbons from the residue of petroleum oils non-volatile *in vacuo* above 300 deg.; the hydrocarbons were identified by specific gravity and molecular weight determinations and by elementary analysis and were found to belong to the series C_nH_{2n-8} to C_nH_{2n-12} . The composition of the heavy fractions of petroleum oils have long remained *terra incognita*, and Dr. Mabery has given many younger investigators a splendid example of patience and courage in undertaking such difficult and time-consuming work.

SOME CHEMICAL CONSIDERATIONS OF PETROLEUM REFINING

Dr. B. T. Brooks, in a paper on "Some Chemical Considerations of Petroleum Refining," made a plea for a closer connection between pure organic chemistry and petroleum technology, and for better dissemination of information now in the files of private organizations. Dr. Brooks pointed out some influences tending to make the oil industry more like what a good industry should be, chief of which is the growing scarcity of crude oil. He characterized present-day practice in oil refining as highly unscientific, and in an interesting review of recent work explained some of the possibilities for technical improvements. Dr. Brooks voiced the opinion of many present when he called attention to the need in this country of a journal resembling the *Journal of the Institution of Petroleum Technologists*, where persons engaged in petroleum work could find both an adequate record of all reliable work and could also be assured of a medium which would bring their researches

to the attention of all those interested. This paper will be published in full in a subsequent issue.

EXPERIMENTS WITH OILS AND OIL MIXTURES

Dr. R. E. Wilson, director of the Research Laboratory of Applied Chemistry at M. I. T., presented two interesting papers. In the first, read by himself, Dr. Wilson explained a very accurate but simple method of determining the initial and various partial condensation temperatures of kerosene- or gasoline-air mixtures. A Socony kerosene mixed with air in the proportion of 14.5 to 1 gave a dew-point of 232 deg. F. at one atmosphere total pressure, and a Socony gasoline under identical conditions gave 97 deg. F. The data were presented for a wide range of conditions. Of great interest were the data which the work supplied on the total heat of kerosene and kerosene-air mixtures. The second paper, jointly with L. W. Parsons and read by Dr. Parsons, described work carried out co-operatively with the Vacuum Oil Co. on a method for measuring the true color of oils, using the Dubosq instrument and giving results on a scale directly related to the Lovibond. The unknown oil was measured in a thin film of known thickness, and compared with varying thicknesses of an oil solution of standard color. The method permits the determination of batch colors from effluent colors during filtration, provided the weight of oil is known.

OTHER PAPERS PRESENTED

Dr. F. H. Garner read a paper written jointly with Dr. W. F. Faragher on "Removal of Hydrogen Chloride From Chlorohydrocarbons." The effect of temperature and various catalysts on this reaction, so important in the preparation of unsaturated compounds, was studied, and a method was presented for the preparation of olefines.

C. J. Rodman presented a new and very accurate method for determining very small percentages of water in transformer oils, depending on evaporation *in vacuo* and absorption by phosphorus pentoxide.

Dr. E. W. Dean and F. W. Lane, of the Bureau of Mines, reported, in a paper read by Dr. Lane, on a study of the variation with temperature of the viscosity of some typical American oils and their fractions. The authors found that their curves could be represented by a general equation, and pointed out that there was no reliable method for calculating viscosities for oils for which less than three values have been determined at different temperatures.

Dr. W. A. Gruse read a paper by W. F. Faragher, F. H. Garner and himself, in which a résumé was given of a study of the measurement of unsaturation in cracked gasolines and unsaturated hydrocarbons by the determination of the iodine number; particular attention was paid to the variation of the iodine number with time and quantity of material.

Dr. W. F. Parish, in a paper presented in his absence by W. F. Faragher, reported on the interesting topic of reclaiming used motor oils; he brought out the fact that the reclaimed oils (mixed with soda ash and blown with steam) were better than new oils, after the removal of absorbed heavy ends of motor fuel, because the high temperatures in the explosion chamber served to decompose the lighter constituents. Dr. Parish brought out the desirability of perfecting a standardized form of reclaiming apparatus which could be used by persons without technical training, and emphasized the

fact that the oil drawn from a motor after a thousand miles' running is not a waste product, but can easily be reclaimed.

Dr. C. E. Waters reported on a continuation of his well-known work on the oxidation of lubricating oils. The paper was read by Dr. F. R. Baxter, and was a study of the catalytic influence of various metals on the oxidation of oils being tested in the Waters apparatus. The influence of copper was so marked that the author closed with a suggestion that transformers be made of zinc or aluminum and that bearing metals should contain no copper.

Division of Industrial and Engineering Chemistry

The meeting of this division, which has always been looked forward to in preceding years with anticipation as a source of profitable information for chemical engineers, was a distinct disappointment to the members who heard the papers presented. While there were several of extreme high merit as scientific presentations outlined in the following paragraphs, the very poor average called forth some caustic comments from the members at the close of the session.

RATE OF DRYING OF SOLID MATERIALS

Those who expected the drying symposium to be worth while were not disappointed in the excellent scientific address delivered by W. K. Lewis on "The Rate of Drying Solid Materials." This paper was the result of seven or eight years' scientific investigation at the Massachusetts Institute of Technology and dealt with the mechanism of evaporation of water from the surface of solids.

All solids hold water adsorbed on their surfaces in moist air. Solids can never be dried below the equilibrium point, which depends on the humidity and the temperature. The only water which will evaporate is the free water. This adsorbed water behaves as though its equilibrium moisture were the same as that of the solids.

For the simplest mathematical example sheet materials were chosen to prove out the process involved.

The accompanying diagram shows a sheet of material under consideration. The distance MN represents the space on this sheet under test. Let this sheet be divided by the center line as shown, then the space included between the lines to the left of the center line represents the original moisture content of the sheet. The line AB represents the average concentration of moisture, or the differential gradient throughout the sheet. It is not really a straight line, but will do for practical industrial approximation.

The moisture within the body of this material must be permitted to get to the surface. Evaporation at the surface and diffusion of moisture from the material are the two processes involved in getting rid of this moisture. Both are really a problem of diffusion, since the moisture must be diffused through the air. There is a difference

in the operation of the process of removing the moisture at low temperatures and high temperatures when figured mathematically. Let w equal the surface concentration of water. Then

$$\frac{dw}{dt} = bx$$

where b is a constant depending upon the drying conditions and x is the moisture content of the surface.

$$\frac{dw}{dt} = \frac{8abw}{(2a + bL)L}$$

When diffusion is rapid as in the case of wood pulp, then

$$\frac{dw}{dt} = \frac{2bw}{L}$$

When the evaporation is slow,

$$\frac{dw}{dt} = \frac{4aw}{L^2}$$

Experimental data were presented to prove this in the form of numerous curves. In the first case time in minutes was plotted against per cent of moisture to show when the moisture content of the solid reached the equilibrium of that of the air. Another curve was presented to show the rate of twine drying.

Most sheet materials shrink when they dry, and allowance must be quantitatively made in the equation when these curves are plotted. Other slides showed the adiabatic air-drying of heel board corrected for shrinkage. The rate of diffusion is proportional to the difference between partial pressure of moisture on the surface and partial pressure of the drying air.

Further curves were presented to show that the rate of drying is inversely proportional to the thickness of the material and that the drying is constant at constant air velocity. The rate of drying then varies with the air velocity.

It was found during these investigations that the ratio of water taken out of the substance to the heat put into the drying operation exactly equals the specific heat of the substance. Materials in which diffusion is slow as in the case of tightly twisted twine, for instance, dried at a rate inversely proportional to the square of the thickness. In the case of soap, where the diffusion is extremely slow, the moisture recedes into the center of the cake, slowing up the drying process. There is no relation between diffusion and the rate as occurs in swift drying shown by the formulæ, which datum confirms the theory given in the first paragraphs. Removal of an organic solvent by drying from fibrous material operates just like drying out of water.

In summarizing, the conditions surrounding the process of drying are: (1) Care so as not to injure material dried; (2) adequate air supply; (3) adequate heat supply; (4) adequate time to complete the process. The first three items are taken care of in industrial drying today, but the fourth is now empirical and the author believes that the time factor may be quantitatively worked out so as to permit the drying of industrial materials on a definite scientific basis.

THEORY OF ATMOSPHERIC EVAPORATION

W. H. Carrier's paper on the theory of atmospheric drying involved the development of numerous drying formulæ, as well as the treatment of the subject from a physical and thermodynamic viewpoint. The work was carried out with particular reference to compartment drying, although the data may be applied to other types.

Since this work involved so many calculations, it would have been better published than read before the members, since it only consumed time. It was impossible to follow the rapid reading of so many calculations.

THE COMPARTMENT DRIER

A. E. Stacey, in collaboration with W. H. Carrier, presented a paper on the compartment drier, treating the subject from a chemical and physical viewpoint. The work contained the operations involved in the process of compartment drying and also covered the method of drying by silica gels. Numerous slides were presented showing all types of compartment driers now installed in the industry.

DIRECT-HEAT ROTARY DRYING APPARATUS

Like the preceding paper, the one given by R. G. Merz, on the direct-heat rotary drying apparatus, covered little material that is not already known to the users of driers. It was an exposition of the different mechanical developments of rotary driers and discussion of the industries where they may be applied. The rotary drier was first developed for the drying of ores in the mining and metallurgical industries and is now finding a wide application in the chemically-controlled industries. It is adapted to installations where large quantities of materials must be dried at low temperatures, when such material will not be injured by continued abrasion in the revolving barrel.

TUNNEL DRIERS

G. B. Ridley spoke from an engineering viewpoint on the installation and operation of tunnel driers as applied to the dehydrating fruit plants on the Pacific Coast. These driers are similar in construction to the well-known tunnel kiln used in the ceramic industries, and may be operated by the application of steam, hot air or direct heat, steam being the most easily regulated where low temperature can be used. Trays of the material are loaded on rack cars, which are in turn wheeled through the long tunnels and submitted to the drying air. Excellent engineering data were presented to show methods of scientific control by charts and diagrams. The tunnel drier is cheap and convenient, will handle any material, can be accurately controlled, etc. It is better to enter the cars at the hot end of the tunnel where the material will stand the high initial heat, because more rapid drying prevents case-hardening or leathery consistency being given the material; and in the case of fruit, maintains the flavor. This drier operates more economically with large air circulation to control humidity. Efficiencies of furnaces or driers range from 92 to 98.5 per cent. Direct heat is the most efficient way if correctly applied.

THE SPRAY PROCESS

R. S. Fleming, of the Merrill-Soule Co., Syracuse, N. Y., talked on the spray process of drying as originally invented in Germany in 1901, for the drying of milk, blood, albumen, etc. The manufacture of powdered milk by this process was started in the United States in 1905. It was later modified to provide for the condensation of the liquid before it enters the driers.

The apparatus needed consists first of an air scrubber to clean the air before introducing to the spray room. The air may be water-washed or better yet filtered through cotton wool layers. Blowers provide the air pressure and in some cases an exhaustor is used on the

finishing end of the system. Steam pipe is placed over which the drying air may be passed and finally a set of sprays operate in the drying chamber where the hot air hits the fine material. This chamber usually consists of a large rectangular room with the liquid sprayed into the air from the ceiling. The atomizer proper may be air-sprays, operated by compressed air or by introducing the liquid under hydraulic pressure. Finally, a dust collector may be installed to operate in conjunction with a filter at the end of the system to save the fine dusts.

In actual operation very intimate mixture of air and particles is secured, causing an intense evaporation on the surface of each droplet. This occurs so rapidly that the droplet is kept cool. It is an especially efficient way to obviate injury by heat where some organic substances are handled. The greatest danger for such substances is when the mass is in the stage between a sirupy and dry condition. This state is passed instantly in the spray-drying process. The expense of drying by this method is too high for inexpensive substances, but where milk, sugar and other organic liquids, including blood and albumen, are to be dried, the efficiency more than overcomes the high cost.

Where concentrated liquid is fed into the sprays larger particles are produced, so that there is less bulk and greater solubility when the substances are to be redissolved in water when used. Among other types of substances glucose has been successfully dried. This paper holds interest for many people who have special problems in drying difficult liquids.

VACUUM DRYING

B. J. Van Marle discussed the subject of vacuum drying and the various equipment used, including rotary, shelf and drum driers. There are no universal driers for any material and the fields overlap. The quantity of product and cost are considerations in deciding which equipment will best handle same. The cost of vacuum driers is high because strength to resist pressure is needed. They are not suitable for large quantities, particularly the shelf type. This paper was a good exposition of the manufacturers' line of equipment in various fields where it is employed.

TESTS OF COUNTER-CURRENT KELP DRIERS

E. C. Spencer described the test on small counter-current kelp driers which showed that the thermal efficiency of the counter-current drier was 78 per cent on a 4-ton drier as compared with 88 per cent on a uni-directional drier.

DISCUSSION ON DRYING SYMPOSIUM

The informal discussion after the presentation of these papers developed the fact that in the spray process of drying usually about one-third of the total solids obtained is collected in the dust collector at the end of the process; also that the particles dry in a spherical condition. Preconcentration affects size of particle more than any variations in the pressure on the spray. Sugar has not been successfully dried by the spray process because the particles land on the floor in a molten condition and therefore form a sticky mass. Glucose, however, behaves admirably.

A. V. H. Mory further brought out that it is better to cause the liquids to boil in vacuum drying. He further developed that in compartment drying in an original design, the air was introduced at the top of the

tunnel at one end and drifted through the material to the bottom of the tunnel at the other. In putting a blower counter-current to the current of drying air an equal distribution of air was obtained through the entire mass or space of the drier. Mr. Stacey attributed this result to the additional amount of air entering the drier, but Dr. W. K. Lewis showed that it was due to the high velocity causing a turbulent motion which brought more of the same air in contact with the material. In other words, when the velocity of air is slow it simply drifts through, drying the nearest edges of the pieces in question, while in the case of a rapid velocity of air it becomes turbulent and presents continually unsaturated portions of air to the wet mass to be dried. The critical velocity from the straight line to the turbulent motion is greater in the case of air than water. Turbulent motion in a drier is exceedingly important.

Crosby Field, of the Allied Chemical Corporation, criticized the types of papers presented in that the manufacturers did not go into mechanical details. In general they design driers by hanging metal around the drying idea, and this metal is not distributed to the best mechanical advantage. Mr. Gertz, of C. O. Bartlett & Snow Co., laid the responsibility for this condition on the purchasers of driers, who buy on cost rather than quality of design. The manufacturers are therefore forced to skin the design down to meet the competition. It was very evident on the whole that the members were not satisfied with this symposium.

Other Papers

METHOD OF TESTING FILTER CAKE OBTAINED IN REFINING VEGETABLE AND ANIMAL OILS

Charles Baskerville presented samples and described the methods for treating filter cake obtained in refining vegetable and animal oils. Crude linters are introduced into the filter cake to act much in the same manner as hair in plaster. When the cake is removed it is treated with sulphuric acid solution and the linters are separated in centrifugals. More than 93 per cent of the 5½ per cent free fatty acid found in the cake coconut oil was recovered. There is a considerable overall saving of free fatty acid, say about 1 per cent, and the process has been installed in six plants which obtain a saving of 6,000 tons per annum. The samples presented showed very excellent recoveries of cottonseed oil, soya-bean oil, peanut oil, coconut oils, etc.

APPLICATION OF THE COTTRELL PRECIPITATOR TO THE WOOD-DISTILLATION PROCESS

L. F. Hawley, of the Forest Products Laboratory, described research carried on in the use of the Cottrell precipitator to recover mists in the wood-distillation process. The so-called dissolved tar which is removed from the pyroligneous acid by distilling off the acids is not a tar like the coal tar consisting of oils and pitch, but is really a pitch containing very small proportions of oil and soluble in the pyroligneous acids on account of the presence of acetic acid and methanol. Such contaminating pitch is carried over in the form of a fog or mist consisting of very fine drops of liquid pitch.

It is found that since the Cottrell precipitator is able to precipitate fine particles of liquid or solids when carried in a stream of gas, it should be introduced into this process, and was therefore connected between the retort and condenser of the small wood-distillation ap-

paratus. During the first run the precipitator was heated so that the vapors at the outlets from the precipitators had a temperature of about 160 deg. C. On examining the inside of the precipitator it was found that a deposit of hard pitch had been built up from the inside surface of the tubes. The temperature of the precipitator was then run near 100 deg. C. to collect the small amount of liquid with the hard pitch. This tar was not very thick even at ordinary temperature and was sufficiently liquid to drain from the tubes without any difficulty.

Although the small-scale experiments have not removed the last traces of pitch and although a satisfactory acetate of lime could not be made from the directly neutralized pyroligneous acid, yet they have shown that the general idea of precipitating tar from hot vapor is a possibility and that in a commercial-scale apparatus the formation of secondary tar may be more complete before the vapors leave the retort, and therefore a purer pyroligneous acid can be obtained by this method. The complete equipment will be described in a future number of CHEMICAL & METALLURGICAL ENGINEERING.

ALCOHOL AND CHEMICAL INDUSTRIES

J. M. Doran, in discussing the use of alcohol in the chemical industries, showed how the present and future development, notably the dye industry, is intimately bound up with the alcohol industry.

The Eighteenth Amendment to the Constitution and the Volstead act affect this key industry far more vitally than the average chemist is aware. Title III of the national prohibition act accords special treatment under the law to industrial alcohol, but overshadowing all are the prohibition features of Title II of the same act, wherein alcohol is defined as intoxicating liquor and made subject to the restrictions surrounding intoxicating liquors. In order to free the alcohol industry and dependent and allied chemical industries from the strangling rules surrounding liquor under which no industry can prosper, it is of utmost importance that alcohol be divested of its beverage character. The handling and use of pure alcohol in any industry is now a liability rather than an asset.

Under the denaturing provisions of the national prohibition act it is possible both to enforce prohibition and to assure the healthy development of industrial alcohol. This may be done by using for denaturant some of the chemicals that subsequently follow in a process where the industrial alcohol is to be used. In other words, select the denaturant for each particular user and introduce it ahead of time, thus preventing the use of the solution for a beverage. This would place the alcohol on a non-beverage basis, thus making the technique more efficient in the disposal of the liquor phase. The educational and research institutions should take this matter up if we are to have a healthy chemical industry.

VALUATION OF OIL-BEARING SEEDS BY FREE FATTY ACID OF THE OIL

Lehman Johnson, in a paper on the valuation of oil-bearing seeds by free fatty acid of the oil concludes that since below 2 per cent free fatty acid a well-settled crude cotton oil is normally prime, making the required color and 9 per cent refining loss, and since above 2 per cent free fatty acid the refining loss on settling oil admits very fairly of a factor, the method presented of the value of the oil-bearing seeds by the percentage of

oil obtained through extraction of the thoroughly dried seed with petrolic ether and determining the free fatty acids from this same extract is quite accurate and fair enough for commercial purposes, and should eventually be substituted for the "cut and count" of damaged seed as now provided by the Interstate Cottonseed Crushers' Association, which says, Rule 2, Section 4: "The percentage of damage shall be determined by counting the damaged and immature seeds." The same method is probably applicable to other oil-bearing seeds where the oil is refined by the alkaline method.

DETECTION OF CARBON MONOXIDE

C. R. Hoover presented a method for the detection of carbon monoxide with apparatus designed for accomplishing same. The importance of the detection of quantities of carbon monoxide physiologically harmful is shown by the large number of deaths each year due to asphyxiation, practically all of which are caused by the presence of this gas. An increasing number of workers in the industries, as well as operators of automobiles and other motor vehicles and users of gaseous fuels, are exposed to this peril. Carbon monoxide is an insidious danger, since it is colorless and odorless, giving no warning of its presence through the unaided senses. In spite of numerous ingenious chemical and thermometric detectors, the effect of the gas upon small animals has been practically the only method successfully employed.

The newly developed apparatus consists of a rubber aspirator bulb attached to a nickelplated brass tube about 6 in. long. A few squeezes of the bulb draws a sample of the air being tested through the brass tube, which contains activated charcoal to remove gases likely to interfere with the test for carbon monoxide, and forces it out through a small glass tube containing a mixture of fuming sulphuric and iodine pentoxide. If carbon monoxide is present, this white solid turns varying shades of green, increasing in depth as the amount of carbon monoxide increases. By comparison with a permanent scale attached to the apparatus the amount of gas present is readily determined. The whole determination requires but a few seconds and after a few minutes the color disappears from the glass tube and the test can be repeated.

More recently an improved device has been constructed. A piston and cylinder with positively operated valve replaces the aspirator bulb. This insures a definite volume of gas for each test and a shorter time for the taking of a sample. The material acted on by the carbon monoxide, which is prepared from iodine pentoxide, fuming sulphuric acid and granular pumice stone, has been rendered more sensitive so that quantities of gas as small as 0.03 per cent can be definitely shown and fairly accurate analyses of amounts up to 2 per cent quickly made. The detector is designed for use in coal and metal mines, industrial plants using or producing gases containing carbon monoxide, garages, telephones or telegraph conduit tunnels, holds and stoke rooms of ships, boiler rooms, etc. In most of these the simple form of detector has already been successfully used. In comparing the results of this detector with chemical analyses, the following results were obtained:

Bulb Method	Piston Method	Laboratory Analysis
0.5	0.6	0.583
.5	.4	.431
.3	.2	.161
.2	.125	.127

MICROSCOPE ILLUMINATION WITH REFERENCE TO BROWNIAN MOVEMENT AND COMBINATION LIGHTING

A. Silverman showed some experiments with the microscope illumination with reference to Brownian movement and combination lighting, the first part of this paper dealing with the Brownian movement. The slide with a hollow-ground depression in which the colloidal solution was placed had dipped into it the lens of the microscope, which in turn was surrounded on the edge of the depression by a circular lamp. On examination it was found that the particles displayed Brownian movement much more distinct than ever before observed.

The second part of the paper dealt with combination lighting to show in proper detail a fossil insect imbedded in amber. In the contrast illumination of this with white background beneath the slide the fossil appeared only as a dark outline with no detail. Placing a black background below the slide some detail was shown, but it mainly appeared as a white outline on the black. The third slide, showing light background with reflected light thrown on the top of the fossil, gave an exceedingly fine illumination of perfect detail brought out by the illumination.

RELATION OF STRUCTURE TO FREE ALKALI IN SODIUM SILICATE SOLUTIONS

William Stericker, of the Mellon Institute, in discussing the relation of structure to free alkali in sodium silicate solutions, stated that the literature was full of contradictions on this subject, and that the textbooks were erroneous. The alkali silica ratio in sodium silicate solution varies from 1:1 to 1:4. It has not been conclusively proved that sodium silicate solutions are independent of the free alkali content. Concentrated solutions are non-hydrolized. When a layer of water was placed on a layer of silicate, fine hair lines were seen to wriggle up through the water, showing there was some substance present which went quickly into solution in the water, and if left to lie long enough, an intermediate layer was formed between the water and the silicate solution. In studying a solution of silicate the sodium hydroxide exists in higher concentration at the interphase than elsewhere. Basic dyes were adsorbed on the surface of the particles, while acid dyes were not adsorbed by colloidal particles. When a basic dyestuff is used as an indicator, it gives the concentration at the interphase. In testing with hydrogen ion concentration apparatus it was found that the alkali is not hydrolized even in dilute solution. It was further found in testing by this method that the concentration of the dilute portions away from the colloidal particles was really determined in the two-phase system.

Colloidal particles may contain electric current, and this current may account for the discrepancy discovered. Heating of the solution affects the degree of hydrolysis.

It is then difficult to determine the amount of free alkali in sodium silicate solution. No general method can be devised. Attention is called to these facts so that any attempt to determine free alkali must be made under the same concentration as that under which the material is to be employed in industrial use—that is, dilute or concentrated—and the temperature of the solution must be kept the same as that in the condition under

which it is going to be used. The Mellon Institute is continuing on this research.

COMPRESSION EVAPORIZATION

Gustav Carlsson gave an illustrated talk on the new method of concentrating liquids developed in Europe recently. This compression evaporation is effected by heating the liquid in containers to boiling point and compressing the evolved vapors, thus raising the temperature.

For complete description of this process see Mr. Carlsson's article in *CHEMICAL & METALLURGICAL ENGINEERING*, vol. 24, page 645, April 13, 1921.

ACTION OF LIME ON GREENSAND

R. Norris Shreve, in discussing the action of lime on greensand, delivered the most complete engineering paper of the session. Greensand or glauconite, found in large deposits along the coast of New Jersey, is treated with lime for the recovery of potash salts. Analyses of this greensand show 3.4 per cent potash, 0.4 per cent soda and 49.8 per cent silica. The Eastern Potash Corporation is building a plant at New Brunswick, N. J., for the recovery of potash and the manufacture of brick from the residue. This plant will treat 1,000 tons of sand per day with about 900 tons of lime to produce 65 tons of potash or an equivalent amount of other potash salts. Ten rotary kilns will be installed with a capacity of 1,800 tons of lime per day and will be equipped with revolving coolers. The lime is added to the greensand in digesters in the presence of water at high temperature and pressure. Caustic soda will be obtained as a byproduct. The liquors from the digestors are run into four large quadruple-effect evaporators for treating the weak caustic solution. These evaporators are 18 ft. in diameter and 55 ft. high. Investigation has been made as to the various methods of handling this greensand and the result of grinding has shown that the best digestion is obtained where 90 per cent passes 200 mesh.

Digestion of the greensand is best carried on under high temperatures. The effect of ratio of water used shows that digestion increases with the amount of water, but it does not pay to handle the water beyond the ratio of one part of lime, one part of greensand to five parts of water. The effect of substituting caustic potash solutions in the ratio of one to one to five of greensand, lime and liquid, shows that the action is retarded somewhat, but nevertheless it is economical to re-use the wash liquors. Five thousand tons of water is handled in the plant daily. The plant is so arranged that the weak liquors treat the fresh greensand and lime and the water from the filter presses is re-used.

Testing variations in the lime ratio at different digestion periods, all tests being made at a high temperature of 470 to 483 deg. F., proved that the ratio can be brought down to 0.85 part of CaO without interfering with the reaction. Investigation was further made with accelerating solutions of various salts such as calcium chloride, sodium nitrate and potassium nitrate.

The plant has a capacity of about 20,000 tons of potash per year, and as the market is somewhat limited other potassium compounds will be produced, particularly potassium nitrate and potassium sulphate. If either one of these latter salts is added to the primary charge, it acts as a catalyzer, or accelerator, and increases the potash yield from 61 to 81 per cent.

It is concluded that for best recovery it is necessary

to grind the glauconite to pass 200 mesh, to maintain the digestion temperature at about 470 deg. F. for one hour, and to use a ratio of greensand, lime and water of 1 to 0.9 to 5. Sodium nitrate was found to be the best accelerator. The product as it comes from the plant is an exceedingly pure one, being equal to the c.p. product of commerce.

WATER RESISTANCE OF TREATED CANVAS DURING CONTINUOUS EXPOSURE TO WEATHER

F. T. Veitch, in discussing the water resistance of treated canvas during continuous exposure to weather, showed that three formulæ gave 100 per cent results. These formulæ involve the use of petroleum, wool grease, beeswax, lead oleate and asphalt. All these increase the resistance of canvas to water as well as to wear in a marked degree.

BUSINESS MEETING

Because of the mass of papers of indifferent value that are being presented before the Industrial and Engineering Chemistry Division it was moved by A. Silverman that the division appoint a committee to pass on all papers before they are accepted for delivery before the division. The chair is to appoint this committee, which will require that the papers be submitted at least two weeks in advance of the meeting. This committee shall have the right to reject any or all papers, and to "bluepencil" such sections of the paper as are deemed of no immediate interest; furthermore, the chair is to have the power to limit the discussion on papers so that in cases where only a few of the members are interested the discussion can be carried on outside of the meeting. The chair shall also have the power to decide whether the papers be read in abstract or in full. The motion was carried.

This action will eliminate the long historical and bibliographical papers that have tired out the members of the division until they left the meetings and missed the points of real scientific and engineering interest.

Dye Division

The meeting was well attended, and the discussion sincere and lively. Most of the papers were of interest only to the dye chemist, although a wider interest attached to some of them. Generally speaking, but with notable exceptions, they lacked that informative value for the development of which the division was established. American manufacturers have not yet got to the point where they dare let very much be said.

The first paper was "A Contribution to the Estimation of H Acid," by Henry R. Lee.

A NEW PROCESS FOR ALIZARINE

The next was "A New Process for Alizarine," by Charles W. Schaffer. This was a preliminary report of laboratory development of a process for producing alizarine with benzene as the raw material. The general interest consists in the fact that it is one of several processes that seem to be coming along to produce alizarine from some material other than anthracene. When anthracene is removed from coal tar according to current practice, the pitch is made unavailable for roofing and road making. Now these uses for pitch are fundamental to the coal-tar industry in the United States, while alizarine is, in effect, the key to the vat dye industry. It is, therefore, of leading importance that a source of alizarine outside of anthracene

be discovered. With abundant alizarine we should not worry about vat dyes in large quantities.

BLEACHING DYED COTTON FABRICS

Dr. J. Merritt Matthews of New York presented a paper on "Bleaching Dyed Cotton Fabrics." This of itself was technical, but the discussion brought out some interesting points. It was generally agreed, as Dr. Matthews said, that the dye industry has been one-sided in its development in this country, with major attention to the making of intermediates and dyes, but inadequate attention to their application. Dr. Derrick of Buffalo confirmed this point, and expressed the wish that the color laboratory at Washington would take up some of the fundamental problems. We are far from adequately informed of the science of dyeing, and we do not know what the actual processes are that take place when a dye attaches itself to a fiber. An immense amount of research in the abstract problem and in the physical chemistry of dyeing is urgently needed, and yet single manufacturers cannot well undertake it. (Our own impression is that unfortunately they do not undertake it.) There are many old dyes that are made in abundance that could be made far more fast and stable and even—in short that could be made far better than they are—by fundamental study, by the exercise of reasonable invention, and by greater care in the dyeing. With this Dr. Matthews was in hearty agreement, and said that the fast colors of antiquity were not due to better dyes, but that the ancient methods of dyeing were more careful, more laborious, and better than ours. Advances have been made in economy at the expense of quality in the art. At this point a gentleman familiar with the textile industry observed that the methods of the dye-houses in mills are deteriorating rather than improving for two specific reasons: The price of coal is such that every process is shortened to the minimum in order to save coal, and the requirements of organized labor are such that the time of men engaged in the work is also made as short as possible.

INDUSTRIAL NEEDS OF CHEMISTRY IN AMERICA

Dr. William J. Hale spoke on "The Industrial Needs of Chemistry in America," and these immediate needs are real chemists. It would have been a godsend to industry if some smart Aleck manufacturers who "have no use for physical chemistry" and who have been scrapping organized research laboratories on the ground that fundamental research is "deadwood" had heard and digested this paper. In some cases, however, it would require a crowbar to aid their mental digestion. Dr. Hale commented with favor on Dr. Derrick's suggestion of co-operation with the color laboratory and other available facilities for fundamental research, and at the Thursday morning session the subject was taken up again.

The chairman, Dr. Davis, recognized that a competent committee to co-operate with the Government laboratories would probably contain men engaged with manufacturing concerns and that it might involve suspicion or misunderstanding of their purposes, despite the best intentions.

Dr. Derrick wasn't worried about that. He said we are inviting ourselves to confer with the Washington authorities, and that the very purposes that the division had in mind were of interest to all manufacturers and users of dyes.

Dr. Alsberg, chief of the Bureau of Chemistry, said that color laboratories were established to render public service, and that the makers and users of colors were its particular public. This public did not have to invite itself; it was already invited.

In regard to the character of research it is almost impossible to get appropriations for that of a fundamental character without giving the specific results that are expected to ensue from it. To impress the mind of Congress any work must be presented to it in terms of money value. It must be translated into dollars. This is always difficult, and sometimes impossible, and yet we can hardly blame Congress for it. It is our business to inform the public of the need of these things, and then Congress will learn from the public. Most of the money appropriated for the Bureau of Chemistry goes to the enforcement of the pure food and drugs act. In order to demonstrate the need of work in pure science for the benefit of legislators Dr. Alsberg had tried to segregate the work in pure science that is being done in order to solve very practical and definite questions, but he found it impossible to make the separation that he desired. The bureau has no appropriation for any theoretical work of which the immediate practical value is not self-evident. He believes that fundamental research is especially the province of the Government laboratories and those of universities and research foundations, while that in applied science is more particularly the province of industries—always, of course, within reason. Another point is that many problems call for years of work; they cannot be solved in an hour; and only the Government is rich enough or long-lived enough to carry them through. We know how pressing is the need of such fundamental knowledge, but the public does not. As soon as we can tell the public of it so that it can understand, then Congress will also understand, and will act. Some industries such as farming, and certain branches dealing in food products, must be helped in a practical way, but in an industry which calls for such meticulous chemical control as that of dyes the information needed is the nature and behavior of reactions, vapor pressure, eutectic points, and fundamental studies within the domain of physical chemistry. Dr. Alsberg said that he, and he believed his successor, whoever this may be, would be glad to give the members of such a committee an official, advisory status, and he believed the Secretary of Agriculture would take the same attitude.

IMPORTANCE OF THE DYE INDUSTRY

Dr. Derrick again referred to the lopsided nature of the industry of which Dr. Matthews spoke because the underlying principles of the uses of dyes are not known. The Germans are working along this line and we are not. There are a great number of scientific problems, fundamental problems that are not understood either here or in Germany or anywhere else. To solve them requires so many different kinds of scholarship that no industrial organization can afford to make the necessary appropriations. And yet the men of just such varieties of scholarship are available in Washington. He was delighted at the broad-minded way in which Dr. Alsberg had presented the attitude of the Bureau of Chemistry. Here is a way to get many of the problems solved. The people interested are the whole public rather than individual manufacturers. Dyes are merely raw materials; the thing desired is good textiles, etc., at once cheap, and dyed, not only

properly, or even in the best way known; they should be dyed in the best way possible, which is an entirely different thing.

COMMITTEE APPOINTED TO SECURE CO-OPERATION WITH THE GOVERNMENT

A great deal of enthusiastic discussion followed for which we have not space, but the general agreement was the need of fundamental research. A motion was passed to create a committee of three, of which Dr. Derrick should be one, to confer with the Bureau of Chemistry at Washington and other available establishments, with the view to planning for co-operation, under all necessary formalities, and under the approval of the governing body of the American Chemical Society. It seems probable that this committee will have the opportunity to succeed in this important work.

Dr. C. R. de Long of the Tariff Commission sent a record of the dyes imported in 1920, which we print elsewhere.

Cellulose Section

This was the first meeting of the section and the crowded attendance, together with the high standard of the papers presented, indicated a widespread interest in the subject. The topic which attracted greatest attention was that of the symposium relating to "Our Future Supply of Liquid Fuel," and the ensuing discussion indicated a lively appreciation of the gravity of the subject. The communication by T. A. Boyd of the General Motors Co. showed that the number of automobiles and trucks in use in the United States has increased from about 1,000,000 in 1912 to about 9,000,000 in 1920, or an average increase of over 1,000,000 a year. Crude oil, the principal source of motor fuel for motor vehicles, has shown an increase in domestic production from around 220,000,000 to 440,000,000 bbl. per year, so that while the number of motor vehicles in use has multiplied about ninefold, the output of domestic crude oil products has only doubled.

The production of crude oil has increased since 1909 about 140 per cent, that of gasoline about 800 per cent, but the number of automobiles registered has risen 2,570 per cent. The consequent enormous demand for gasoline has been met, partly by increasing the boiling point range, partly by extracting liquid hydrocarbons and partly by cracking. According to the U. S. Geological Survey the unmined supply of petroleum is roughly 6,000,000,000 bbl., which, if the present rate of production is maintained, will be exhausted in about thirteen years. From these figures it is apparent that some other source of liquid fuel must be found, and cellulose in the form of plant life appears to offer interesting possibilities.

POSSIBILITIES OF THE TROPICS TO FURNISH MATERIALS FOR CELLULOSE AND CARBOHYDRATES

It was shown by H. N. Whitford, professor of tropical forestry, Yale University, that a possible solution is to be found in the utilization of the solar heat of the tropics for the growth of cellulose materials such as cassava, nipa palm and especially bamboo. Thus an area in the Philippines of about 63,000 square miles, if planted with selected species of bamboo, might be expected to yield cellulose material from which an amount of alcohol equivalent to the present annual consumption of gasoline could be obtained. Other interesting data relative to cassava and the nipa palm were

given, as for instance that the present annual product of "nipa alcohol" from quite a small area in the Philippines amounts to 3,000,000 gal.

POSSIBILITIES OF A FUTURE FUEL SUPPLY FROM OUR FORESTS

R. C. Hawley, also of Yale University, pointed out that the forest resources of the United States are capable of supplying waste wood annually to the amount of 11,000,000,000 cu.ft., equivalent to 2,475,000,000 gal. of a colloidal fuel to be obtained by peptization of a entirely neglected.

In view of the important results recently obtained by F. B. LaForge of the Bureau of Chemistry on the production of furfuraldehyde from corn cobs, it was of interest to learn that if the total waste cellulose material represented by the corn stalks and cobs could be utilized for the production of furfuraldehyde, it would yield approximately 3,900,000,000 gal., or sufficient to replace our present supply of gasoline. The material has been tried out as a motor fuel and has the great disadvantage of causing pre-ignition in the motor, but it is confidently believed that this could be overcome.

In the subsequent discussion of the papers and of the part to be played by the chemist attention was drawn to the possibility of two solutions of the fuel problem: (a) the joint production of furfuraldehyde and alcohol from some suitable available raw material, and (b) the use of a colloidal fuel to be obtained by peptization of a material such as cellobiose by means of alcohol, the former to be obtained by the bacterial decomposition of wood. In view of the necessity which would arise, in attempting to use such a colloidal fuel, of altering the entire design of the engine to the Diesel type, earnest consideration should be given to the cheapest sources of supply of alcohol and furfuraldehyde. In the first place it is not practicable to use domestic cereals, as this would interfere too seriously with the nation's food supply, but the utilization of cornstalks and cobs, waste wood and, further, of the growth in the tropics of something in the nature of a cross between a cereal and a tree species in order to obtain (as stated by one member) "a kind of bamboo filled with starch" is what is required as a source of raw material. The problem is a fascinating one for the cellulose chemist and offers abundant opportunity for research work and the exercise of the imagination.

EFFECT OF ADDING VARIOUS CHEMICALS TO WOOD, PREVIOUS TO DISTILLATION

The paper of L. F. Hawley on the effect of adding various chemicals to wood, previous to distillation, showed that an increase in the yield of products could be obtained by subjecting the wood to a previous treatment with 0.5 per cent of sodium carbonate. Curiously enough, the sodium remains combined as carbonate at the end of the operation.

In the discussions relating to the manufacture and commercial application of nitrocellulose it developed that there is no recognized standard method for determining the viscosity of such solutions and a committee is to be appointed of those interested, with G. E. Esselen as chairman and E. Bingham as consultant, to work out the details of a standardized, acceptable procedure.

The value of the work being carried out at the Forest Products Laboratory on cellulose materials has been recently recognized, on the one hand by the increased

Government grant of \$100,000 and on the other by the contribution of the American Paper and Pulp Association. It is considered highly desirable that the chemists should have time available for the compilation of monographs and special theoretical papers and the following resolution was adopted by the section and ordered forwarded to the director of the Forest Products Laboratory:

"The Cellulose Section of the American Chemical Society, in session at Rochester, N. Y., congratulates the director on the increased Government grant and looks forward to increased activity in the matter of the acquisition and publication of fundamental scientific data and monographs."

The chemical changes involved during the infection and decay of wood pulp, by Bray and Staidl, also of the Forest Products Laboratory, brought out the immense financial loss caused by this factor and threw light on the nature of the changes occurring. It is this phase of the subject which is being financed by the A.P.P.A.

THE MICROSTRUCTURE OF WOOD

One of the interesting contributions was that by Allen Abrams on "The Microstructure of Wood," this work having been financed by the Meade Paper and Pulp interests and carried out at Massachusetts Institute of Technology. It represents a new technique by means of which chemical changes in the cell structure taking place under the influence of chemical and other reagents can be readily followed from a study of microscopic sections stained or otherwise treated.

EUROPEAN PRACTICE IN CELLULOSE ACETATE AND DOPES DURING THE WAR

It was brought out in the communication on "European Practice in Cellulose Acetate and Dopes During the War," by Philip Drinker, that there exists a mass of valuable information accumulated by E. C. Worden and himself during 1914-19 in a special Government report which they presented on the subject. A resolution was passed unanimously by the section urging the Government to publish such information in the report as is not regarded as confidential, since it is considered that this would be of great value to the industry.

ACTION OF HYDROBROMIC ACID ON CELLULOSE AND RELATED DERIVATIVES

In the paper dealing with "The Action of Hydrobromic Acid on Cellulose and Related Derivatives," by Harold Hibbert and Harold S. Hill, higher yields of bromomethyl furfuraldehyde were recorded than obtained by Fenton. The fact that dextrose gives a yield of 10 to 15 per cent of the same crystalline derivative destroys the value of this reaction as an argument for the ketonic structure of cellulose.

A PROPOSAL FOR A STANDARD CELLULOSE TO BE AVAILABLE FOR RESEARCH

A paper by B. Johnsen, of the Hammermill Paper Co., on "A Proposal for a Standard Cellulose to Be Available for Research" gave rise to an animated discussion. The author suggests the advisability of having the section arrange for the manufacture of a considerable amount of an especially pure cellulose to be available for the cellulose chemist and by the general use of which for research purposes strictly comparable results would be obtained. It was stated that the Atlas Powder Co. had expressed its willingness to manufacture the material.

A committee was appointed, consisting of B. Johnsen, a representative of the Atlas Powder Co. and the chairman of the Section (with power to add to their number), to draft a tentative scheme of purification, the chairman agreeing to bring this to the attention of interested parties for their criticism and comment and to have the matter referred to the Section for final action at the September meeting in New York.

Rubber Division

When one considers the great depression which has existed in the rubber industry for the past six months the Rubber Division was very fortunate in having any spring meeting at all. Only two papers were presented from manufacturers' laboratories. All the others came from the universities, the Bureau of Standards or makers of materials. However, the sessions were well attended by about fifty interested men and women. Evidence of constructive thinking and fair mindedness was manifested in the discussion which followed each paper.

TENTATIVE PROCEDURE FOR THE ANALYSIS OF RUBBER GOODS

Tentative methods of analysis, compiled by W. W. Evans from the methods of the joint rubber insulation committee, the Bureau of Standards and the underwriters' laboratories, had been mailed to all members of the Division previous to the meeting. The discussion took the form of outlining various profitable changes in the methods as presented. These changes were referred to the analytical committee, which is composed of the following men: Messrs. Collier (Bureau of Standards), Dugan (Goodyear), Wiegand (Ames Holden MacCready), Simmons (Akron University) and Evans (Goodrich). Very briefly the methods adopted are as follows:

Acetone Extract—Use underwriters' apparatus and method except dry to constant weight at 70 deg. C.

Unsaponifiable Material in Acetone Extract—The committee is to determine once and for all whether alcoholic soda or potash is preferable. Otherwise the method is similar to that of the joint rubber insulation committee. Calbeck proposed treating the alcoholic soda solution with a small amount of silver nitrate to decompose any aldehydes. His solution keeps longer without discoloring. In all such determinations running a blank is strongly recommended.

Free Sulphur—Name changed to "Soluble sulphur." Regular bromine oxidation method recommended.

Chloroform Extract—Usual procedure.

Alcoholic Potash Extract—Usual procedure, but comments under "Saponifiable matter" apply here.

Total Sulphur—Bureau of Standards method. Caution: use only the bromine saturated nitric acid solution and allow no free bromine to come in contact with the sample.

Ash, Sulphur in Ash, Barytes—As per underwriters' practice.

THERMAL CONDUCTIVITY OF SOME RUBBER COMPOUNDS

A paper on "Thermal Conductivity of Some Rubber Compounds" was read by A. A. Somerville. A series of thin sheets of rubber with thermocouple junctions between were placed on a steam chest kept at 100 deg. C. On top of this pile a vessel containing melting ice maintained a temperature of 0 deg. C. By comparing the time necessary for the center thermocouple to reach

maximum temperature for various stocks a measure of their relative heat conductivity was obtained. The conductivities of stocks containing 3 and 10 per cent sulphur on the rubber and 10 per cent sulphur with 2 per cent accelerator were found the same. This value was taken as unity. The following table contains the values obtained with 10 per cent sulphur, 2 per cent accelerator and 150 per cent zinc oxide or its equivalent volume of other filler based on 100 parts of rubber:

Base stock	1.00
Zinc oxide (150 per cent)	1.65
Glue	.87
Asbestine	.91
Lampblack	1.02
Gas black	1.14
Crimson antimony	1.15
Whiting	1.23
Lithopone	1.33
Magnesium carbonate	1.45
Soapstone	1.45
Clay	1.67
Litharge	1.78
Red oxide	1.86
Fossil flour	1.90
Barytes (ground)	2.28
Barytes (precipitated barium dust)	2.65
Frictioned fabric	1.07

The state of cure of the various stocks was found to have no effect on the conductivity.

CONTRIBUTION TO THE KNOWLEDGE OF THE RESINS OF HEVEA RUBBER

G. Stafford Whitby and J. Dolid presented a paper entitled "Contribution to the Knowledge of the Resins of Hevea Rubber." By the use of glacial acetic acid certain crystalloids have been isolated from the acetone soluble portion of hevea rubber. Constituent A gives an acetate soluble in chloroform melting at 80 deg. C. The insoluble portion melts at 169 deg. C. Constituent B melts at 62 deg. C. and C melts at 128 deg. C. Its formula is $C_{27}H_{44}O$. Dr. Whitby has definitely established the presence of a rare sugar, quebracheetol, which is related to inosite, and has the following structural formula:

SOLUBILITY OF GASES IN RUBBER AS AFFECTING THEIR PERMEABILITY

"The Solubility of Gases in Rubber as Affecting Their Permeability" was treated in a paper by C. S. Venable and Tyler Fuwa. Many years ago Graham proposed that the permeability of a gas through a membrane depended on, (a) the concentration and (b) the rate of motion of the molecules. In other words, that $P = K \times C \times D$, K being a constant. Transposed to our present terminology this means that the permeability P equals the pressure p times the square root of the molecular weight divided by the solubility S .

N_2 , CO , O_2 and CO_2 give fairly good constants. But hydrogen, methane and ammonia are badly out of line. This has led the authors to propose that an additional factor depending on the size of the molecules of the respective gases should be incorporated in Graham's formula.

Summarizing: 1. Rubber holds gas by true solution.

2. The solubility is directly proportional to the pressure.

3. Solubility decreases with increase in temperature.

4. The solubility is independent of the degree of vulcanization.

5. There is a relation between solubility and permeability, of which size of the molecules is probably a factor.

ANALYSIS OF RUBBER GOODS CONTAINING ANTIMONY SULPHIDE

S. Collier and M. Levin described a method of analysis of rubber goods containing antimony sulphide. The method involves separation of fillers by means of cymene, and solution in acid. Antimony is separated by means of H_2S and determined in the regular way.

THE DIRECT DETERMINATION OF SULPHUR OF VULCANIZATION

S. Collier and M. Levin presented a paper on "The Direct Determination of Sulphur of Vulcanization." Sample is acetone extracted, then dissolved in cymene. Fillers are removed by centrifuging and filtration. The soluble portion is evaporated to dryness and sulphur is determined in the usual way with nitric acid and bromine.

It is somewhat doubtful if this method gives in all cases the true sulphur of vulcanization. The sulphur combined with MR and substitutes apparently would be included. The method doubtless has applications in pure gum stocks or cases where the composition is known.

VOLUME INCREASE OF COMPOUNDED RUBBER UNDER STRAIN

At the Philadelphia meeting a year and a half ago H. F. Schippel pointed out that compounded rubber increases in volume when strained. He demonstrated this fact by indirect methods. Henry Green has been able to observe and photograph, by means of the microscope, the actual changes which take place. Working with rather coarse barytes, he obtained cavities at either end of the barytes crystals. He noted that some particles developed cavities when the piece containing them was stretched, but some did not. In seeking an explanation of this he advanced the theory that many of the particles were surrounded with an adsorbed film of air. In such cases the rubber did not adhere to the crystal. In other cases when this film was absent there was adhesion between the rubber and crystals and no cavities were obtained.

Speaking of zinc oxide Mr. Green stated that in a stock containing 100 volumes of zinc oxide to 100 volumes of rubber no agglomerates were discernible under the microscope.

INFLUENCE OF PIPERIDINE-PIPERIDYL-DITHIOCARBAMATE ON VULCANIZATION

G. Stafford Whitby and O. J. Walker described experiments on the influence of piperidine-piperidyl-dithiocarbamate on vulcanization. The experiments were performed in the absence of zinc oxide. In a high sulphur stock (10 per cent sulphur on the rubber) piperidine-piperidyl-dithiocarbamate becomes a mild accelerator with excellent aging properties. With zinc oxide it is very powerful.

A RAPID BOMB METHOD FOR DETERMINING SULPHUR IN RUBBER COMPOUNDS

Experiments using a bomb made by the Standard Calorimeter Co. of Moline, Ill. (the manufacturer of the

REPORTS OF COMMITTEES

Abstracts—Arrangements have been made with the trade papers to carry any articles the division wishes published.

Accelerators—About fifteen accelerators are now on the books of the secretary and the members of the Rubber Division can secure the composition of these by writing him.

Physical Testing—The old committee was discharged and the following men appointed on a new committee: Messrs. North (Goodyear), Wiegand (Ames Holden MacCready), Collier (Bureau of Standards), Grafton (Quaker City) and Simmons (Akron University).

Division of Physical and Inorganic Chemistry

The schedule of this division was too ambitious, having almost three times as many papers as the average group at the meeting and dividing the time for presentation and assimilation into insufficient periods. At least forty of the sixty-five papers should have been read only by title, giving the important contributions time for detailed consideration.

The fifteen papers in the Symposium on Contact Catalysis in themselves brought out nothing extraordinary in the way of ideas and were exceeded in value by the discussions of Messrs. Langmuir, Taylor, Forbes, Fink, Weiss and Bancroft. Dr. Langmuir introduced the idea that the boundary between the two phases of the catalyst probably located the zone where the reaction takes place. In the equilibrium between the metallic and oxide phases of copper or nickel ideal conditions from the point of view of the oscillation theory are to be had for catalysis. Without this boundary phase, no appreciable reaction takes place, so that this conception promises at least to augment if not entirely supersede the long-honored adsorption theory. However, the experimental work of the investigator is made even more difficult by this conception, especially if he attempts to make quantitative measurements on anything other than the velocity of his catalyzed reaction. A survey of phase boundaries doesn't seem to be even a remote possibility and even if it were, there is no reason to believe that the activity would be equally distributed over the more or less accessible areas between the two phases. The removal of water of crystallization from salts in a desiccator is not usually thought of as a catalytical phenomenon, but it has been proved to be such, the presence of both the hydrous and anhydrous phases being essential before the water goes off under normal conditions. Superheat or a scratch will induce the latter phase. The same phenomenon takes place in the calcination of limestone. Copper oxide is not reduced by hydrogen until metallic copper is formed and the reaction takes place at the location of the contact between the metal and oxide.

HIGH-TEMPERATURE NICKEL INACTIVE

When nickel catalyst is heated above 600 deg. C. it gradually falls off in hydrogen adsorption, becoming inactive at 1,000 deg. C. R. M. Burns and H. S. Taylor presented curves showing measurements made at Princeton. In studying copper it was found that the hydrogen adsorption was very low. A physical study of all the hydrogen catalyzers is being made in their laboratory and detailed attention is being given to the phase systems and catalyst surfaces.

In the discussion Irving Langmuir pointed out that

the electron may be an important factor, present theory of valence and chemical combination indicating that molecules are held together by electronic forces. John Morris Weiss drew attention to the lack of knowledge of what temperatures exist at the surface of the catalysts and suggestions were made that they be calculated from reaction heats or measured by fine platinum resistance wire. It is rather doubtful if any useful result can be obtained by such methods.

INFLUENCE OF AGITATION ON REACTION VELOCITY

R.p.m.'s as a catalyst formed an interesting contribution by C. H. Milligan and E. Emmet Reid. Whether every influence that increases the velocity of a reaction is to be taken as catalytical phenomenon is a disputed question. Most chemists prefer to class mass, temperature, concentration and agitation in a category by themselves. The authors observed that with agitation at 1,000 r.p.m. benzene absorbed 80 c.c. of ethylene per minute, forming ethyl benzene and at 13,000 r.p.m., 1,790 c.c., the same conditions of saturation being taken for comparison. Final saturation produced hexa-ethylbenzene.

CATALYTIC COMBINATION OF HYDROGEN AND OXYGEN

R. N. Pease and H. S. Taylor reported their study of the influence of reduced copper oxide catalyst on the reaction of hydrogen and oxygen mixtures below combustion temperatures. The stability of copper oxide in hydrogen at 150 deg. C. was found to be very great, no reduced copper appearing until after four days, when a small spot appeared. The presence of 2 per cent water or oxygen prevents the formation of any reduced copper. In the catalytical reaction between the hydrogen and oxygen, the boundary phase between the oxide and metal is accepted as the location of the catalytical effect, giving a fluctuating equilibrium.

In the production of hydrogen from water-gas considerable trouble is had in obtaining a product free from carbon monoxide. N. A. Neville and H. S. Taylor have worked on a reaction using potassium carbonate as a catalyst, whereby carbon dioxide is obtained at temperatures around 500 deg. C. An explanation of the phenomenon cannot be had by simply assuming that the salt absorbs carbon dioxide and thus induces its formation. Perhaps its effect on the carbon itself in maintaining temperature and surface uniformity induces the reduction of the gaseous water by the carbon monoxide.

OXIDATION AND REDUCTION IN COPPER CELLS

In refining copper in electrolytic cells a large part of the current is ordinarily spent in oxidation at the graphite anode and reduction at the cathode, if iron sulphate is present in the electrolyte. Colin G. Fink reports that if ferrosilicon anodes are used, the phenomenon ceases, indicating that there is some inherent property in graphite, perhaps oxy-graphite, that catalyzes the oxidation phenomenon and prevents oxygen being given off at the anode.

LOW-TEMPERATURE BRIN'S REACTIONS

James Kendall and F. J. Fuche have recently found that mixed oxides of silver, mercury and barium yield their peroxides at very much lower temperatures. Sufficient work has not been done to tell if the effect were partial or complete and if the reaction will be valuable in making a modified Brin's process for the separation of oxygen from air.

STRUCTURE OF THE ICE MOLECULE

Dennison has recently shown by X-ray crystal analysis that ice consists of two water mols with the electrons arranged in a hexagonal packing. A structure was proposed by Irving Langmuir in which the nuclei of the four hydrogen atoms hold by their fields of force the two oxygen cube atoms, the hydrogen electrons filling the shell of the oxygen atom and the nuclei being sandwiched in between.

PURIFICATION OF HELIUM

When helium becomes loaded with air after it has been in use through diffusion of the latter through the balloon fabric, it can be purified by a process recently developed by Leo Finkelstein and C. B. Seibel. The mixture is cooled below the critical temperature of nitrogen and filtered through adsorption carbon, which takes up both the oxygen and nitrogen. The refining plant is mounted on two railroad car trucks and can be moved to the various aviation fields.

INFLUENCE OF GELATIN ON TRANSFERENCE NUMBER OF H_2SO_4

Alfred L. Ferguson reported a correction in the transference number of sulphuric acid, now in the literature as 0.177, the new determination being 0.1868 at 25 deg. C. In studying the influence of gelatin, it was found that the gelatin formed a true salt with the anion and changed the transference due to the low velocity of this complex cation. The concentration cell method was used with the formula:

$$E = \frac{2 - 3n_a}{2} \frac{RT}{F} \ln \frac{c_1}{c_2}$$

THE ALKALINITY OF SEARLES LAKE BRINE

The alkalinity of the brine at Searles Lake is due to the weak acid soda salts: the carbonates, bicarbonates, borates and metaborates. The total CO_2 content averages around 1.84 per cent and the B_2O_3 1.04 per cent. In order to determine the salt composition, the p_H curve of each salt was determined, from which it was possible to calculate the composition from the hydrogen ion concentration of the raw brine.

THE VAPOR DENSITY OF TECHNICAL PHOSGENE

Phosgene constants were reported by F. O. Germann and Vernon Jersey, the boiling point being 8 deg. C., vapor pressure at zero 552 mm. and the vapor density 4.5263 g. per liter. It was observed that the rate of hydrolysis was proportional to the wet surface area. When the phosgene was passed over wet glass beads, the hydrolysis was instantaneous, while if water was poured into the liquid phosgene, the reaction proceeded only at the interfilm.

CHROMATIC EMULSIONS

Chairman Harry N. Holmes entertained the division with experiments on the dispersion of light into its color elements by transmission through globules formed by digesting glycerine, water, amylacetate, benzene and pyroxylin into an emulsion. The size of the particles did not appear to be a factor, but the glycerine concentration was important. The pyroxylin stabilized the emulsion, forming a strong film surface around the globules. In daylight the dispersion effect is lost due to the mixing of the rays, but with light from a single source the phenomenon is very beautiful.

Kodak Park Works

Kodak Park, the largest of the five Rochester establishments of the Eastman Kodak Co., is a park of 225 acres situated just within the northerly limits of the city. Eighteen of these acres are laid out in trees, shrubs and lawn. Its principal products are photographic film and papers, dry plates, chemicals and developers. Factories are also maintained for the manufacture of raw paper, gelatine and acids (nitric and sulphuric) for nitrating purposes, also for the manufacture of wood, paper and fiber boxes, cartons, tin containers, film spools and wood parts for cameras. Steel and concrete buildings to the number of 114, representing an additional floor space of over 80 acres, have already been erected for the manufacture of these various products.

FILM CAPACITY

Some conception of the extent of Kodak Park and the various ramifications of the photographic industry it contains may be gathered from the fact that the output in motion picture film alone for last year was over 50,000,000 ft. per month or, roughly, 125,000 miles for

COTTON DRIER

the year. Into the manufacture of this and other film goes nearly 3,000,000 lb. of cotton per year, and into the sensitizing of Eastman products over three tons of pure silver bullion every week, or one-twelfth of all the silver mined in the United States.

POWER AND LIGHT

Power and light are furnished by two turbine and four engine-driven electric generators, with a total capacity of 4,500 kw., or 6,000 hp. Another 2,400 hp. is furnished by the Rochester Railway & Light Co.'s plant; 2,250 motors are required to operate the machinery in the buildings. The power house contains twenty-two boilers with a total (rated) boiler capacity of 7,800 hp.

Above the boilers are the coal bunkers, with a capacity of 3,200 tons. From these the coal drops through chutes to mechanical stokers at the rate of upward of 400 tons per day. Waste gases from the furnaces pass through fuel economizers and ashes are removed by a mechanical conveyor.

Two chimneys, which tower above the power house and dominate the landscape for miles around, have a

NITRATING SILVER

combined capacity equal to 20,000 boiler horse-power. Each is 366 ft. high; one measures 28 ft. at the base and 11 ft. at the top, and the other 31 ft. at the base and 15½ ft. at the top. These chimneys were built high to carry off any possible fumes from nitration.

REFRIGERATION PLANT

As moisture or variation of temperature would be fatal to uniform film quality, the great rooms in which film is sensitized and handled are kept at even temperature by a constant supply of cold air. Refrigeration for this purpose is maintained by six ammonia compression machines of 2,650 tons capacity, and twelve ammonia absorption machines of 1,700 tons capacity, a total of 4,350 tons—sufficient for a city of 200,000 people. A fire department is maintained with 150 trained men under the direction of a chief and two deputy chiefs. They live in close proximity and are available at all hours. The fire equipment includes a White motor truck, chemical engine, three hose carts, hook and ladder truck, salvage and tool wagons, pulmotors, smoke helmets, diving suits and all the minor paraphernalia attaching to such equipment. In addition to this, twenty-seven hose houses are located over hydrants outside various buildings, each equipped with 250 ft. of 2½-in. hose.

WATER SUPPLY

The works have an inexhaustible private water supply system connected directly with Lake Ontario, six miles away. A pumping station on the lake shore, with a capacity of 16,000,000 gal., pumps the water through a 24-in. main to a 5,000,000-gal. reservoir in the park. The pumping station there, with a capacity of 12,000,000 gal.—sufficient to supply a city of 150,000 population—maintains a pressure of approximately 100 lb. throughout the park. A steel tank with a capacity of 150,000 gal., built 150 ft. above the reservoir, and two auxiliary fire pumps with a capacity of 1,000 gal. each, are additional fire precautionary measures. Sixty-eight hydrants and four miles of 6, 8, 10, 12 and 16-in. mains gridiron the works.

WELFARE WORK

The attitude of the company toward its many thousand employees is reflected in the numerous provisions for their comfort and physical well-being. These begin with park surroundings; they include lunch facilities, recreation grounds, medical service, dental service,

reading and rest rooms, and all the other welfare features of a modern industrial plant.

RESEARCH LABORATORY

Picture making has been made the simple pastime it is only because the results of careful investigation into the behavior of photographic products have been transferred with equally scientific exactness to the sensitive materials employed. The right arm of the photographic industry is consequently the laboratory, and the company maintains one of the most completely equipped and best staffed industrial laboratories in the world.

The laboratory building itself is 80 ft. square, three stories in height, and employs a staff of one hundred and twenty. In addition to testing laboratories, X-ray rooms and studios, the building is equipped with an independent plant for the manufacture of photographic material on such a scale that the results can be practically applied in the manufacturing departments. Here also are made the photographic materials required for scientific work, for which, of course, there is little or no commercial demand. There is no attempt to limit laboratory investigation to purely practical ends, and the results obtained are available for publication in the same way as university and government laboratories publish theirs.

PHOTOGRAPHIC LIBRARY

A large photographic library, in charge of a trained librarian, is maintained in connection with the laboratory. Practically every important photographic work in English as well as in foreign languages may be found among the 6,500 volumes on its shelves. A large number of books and magazines on kindred subjects are also included.

FILM MAKING

The first process in film making consists in thoroughly washing cotton with caustic soda to remove vegetable gum and other impurities. This is done in large rotary vats. To eliminate moisture the cleansed cotton is then passed through huge driers. It is then "treated" with a mixture of nitric and sulphuric acid to produce cellulose nitrate. Nitrating centrifugals are used for this process. These machines consist of "perforated baskets" rotating inside a vat. The cleansed cotton is fed into the basket and acids are let into the vat until the cotton is immersed. The acids are then immediately drawn off and the basket is rotated at high speed for draining.

SILVER BULLION (KODAK PARK USES ONE-TWELFTH OF ALL THE BAR SILVER PRODUCED IN THE U. S.)

NITRATING COTTON

To remove every trace of acid, the nitrated cotton is then put into huge washing machines, which are a combination of washing machine and wringer. The construction is similar in principle to the nitrating centrifuga's. The nitrated cotton contained in perforated baskets is immersed in vats of water, and the water drained off after each rinsing. The wringing is done by rotating the baskets at high speed. These washings are repeated for several weeks.

FILM "DOPE"

Washing and drying completed, the nitrated cotton is ready for the solvents. These solvents are run into "mixers" and the cotton is fed into them through chutes. In the mixers—sometimes called dough machines—large paddles churn the cotton and solvent together thoroughly. When thoroughly mixed, the solution is a viscous liquid called "dope."

This "dope" is piped to large air tight tanks, where it is kept ready to be converted into sheets. This is done on what are known as coating machines. An elaborate system of filters spreads the mixture evenly on highly polished wheels, where it forms a sheet 3½ ft. wide, 2,000 ft. long and 0.005 in. thick.

This sheet, when dry, becomes the familiar transparent film backing or base on which the sensitized coating is spread. The accuracy of these machines is

DOPE TANKS

such that the variation in thickness of a sheet from end to end, when coated, is not more than the $\frac{1}{2,000}$ part of an inch.

SILVER NITRATE

Silver is the active element in the light sensitized material with which film is coated. Pure silver bullion is first dissolved in diluted nitric acid to form silver nitrate. When evaporated, this is reduced to white crystals, which are carefully washed and redissolved until all trace of impurities is removed. The pure silver nitrate crystals are then placed in trays, a thousand ounces to a tray, and stored in aluminum drying closets.

The compound sensitive to light, known as silver bromide, is formed by mixing these nitrate crystals with potassium bromide and gelatine, dissolved in hot water. This gelatine solution, known as the "emulsion," is spread on the film in emulsion coating machines. This coating is, of course, a dark-room operation, as is the mixing of the "emulsion" itself.

From the slitting machines the film goes to the spooling room, where it is wound on cartridges. Motion picture film is reeled in 200 and 400 ft. lengths, and when so spooled and packed is ready for shipment.

Excursions were made to other plants, including the Taylor Instrument Cos., Pfaudler Co., Bausch & Lomb Optical Co., Rochester Gas & Electric Corporation, Bastian Bros., Vacuum Oil, Bartholomay Co. and the municipal disposal plants.

Exhibits at Mechanics Institute

One of the pleasing sidelights of the meeting was the number of exhibits of local manufacturers shown in the hallways at Mechanics Institute, where the convention divisional meetings were held. The R. J. Strasenburgh Co. showed a case of standardized pharmaceuticals. The Pfaudler Co. exhibited special pieces of glass-lined apparatus including condenser, enameled steel agitator, enameled kettles, reducing ell and observation glass for viewing the interior of a tank containing liquid.

Grahame Chemical Co., of Rochester and Liverpool, England, showed a complete set of apparatus for hydrogen ion determination together with a series of indicators to be used. The Taylor Instrument Co. of Rochester had a large glass showcase in which were displayed the Tycos line, including thermometers, hydrometers, recording instruments, compasses and the cyclo-stormograph.

By far the largest exhibit was a very complete layout of scientific apparatus handled by the Will Corporation, with headquarters in Rochester. This included the complete line of the products of the Torsion Balance Co., in charge of A. T. Millroy; a glass-blowing exhibit in charge of Frederick Kraissl, of the Corning Glass Works. Numerous pieces of pyrex glass were formed by the blowers. Christian Becker, Inc., had a section displaying balances and weights of precision. W. B. Valentine was in charge of the section for the Valentine-Abbe Refractometer which was on exhibit.

Other displays by local concerns of varying interest to the chemists were a case of organic chemicals manufactured by the Eastman Kodak Co., optical measuring instruments produced by the Bausch & Lomb Optical Co., samples of Filtros by the General Filtration Co., forgings and castings by the General Railway Signal Co., motors by the Northeast Electric Co., and telephones by the Stromberg-Carlson Co.

Symposium on Corrosion of Metals and Alloys

Copper-Bearing Steel and Perhaps Steel With Other Alloying Elements Resist Atmospheric Corrosion Better Than Ingot Iron, But the Latter Excels When Immersed in Water—Oxygen and Carbon Dioxide Cause Most Damage in Steam and Hot-Water Piping

ALTHOUGH the problem of corrosion is one of the oldest that has confronted engineers, it is only within the last generation that the problem has been very seriously considered. There has been an ever-increasing use of steel and sheet metal in construction, and new and special alloys have been introduced for a host of modern-day mechanisms and devices. Bridges, ships, roofs, agricultural machinery, telegraph and trolley poles, conveyances, storage tanks, etc., all of which were formerly constructed of wood, are now made of steel or iron. The keynote of the Electrochemical Society Symposium was the emphasis on the practical side of the problem. While some of the papers dealt with the question of producing a corrosion-proof metal or alloy, other papers covered tests on simple methods to protect the metals now available.

For the sake of convenience and aside from any scientific basis we may classify the various corrosion studies under the following headings:

1. Corrosion of metal roofing—atmospheric corrosion.
2. Corrosion of pipes, rods, wires, imbedded in moist soil.
3. Corrosion of boiler tubes and hot-water pipes (closed systems).
4. Corrosion of metals submerged in sea water or acid liquors.
5. Corrosion of metallic anodes.

There is another type of corrosion met with in the case of metal electrodes in vacuum apparatus such as audions, Moore tubes, cathode ray tubes, etc., which, however, though similar in many respects, is usually not classified as corrosion, since oxygen and moisture are practically absent or play but a secondary rôle.

In all of the above five cases corrosion is of the electrolytic type, the electric current being produced either (1) by local couples composed of two or more different constituents in the same metal or alloy; (2) by a couple formed by the union or contact—immediate or distant—of two entirely distinct metals or alloys (as for example, a copper sign plate attached to a steel-re-enforced-concrete wall); (3) electrolytic action may be due almost entirely to stray currents from neighboring service lines; or (4) the electric current may be intentionally applied, as in the case of anodes in acid liquors.

COPPER-STEEL EXPOSED TO THE ATMOSPHERE

Of the iron and steel papers presented at the symposium almost every one of them took up the question of the effects of small copper additions. D. M. Buck of Pittsburgh¹ carried out large-scale tests at Scottsdale, Pa., extending over a period of about three years on 16-gage iron sheets, containing various percentages of copper and exposed simultaneously to the weather. In general, Buck finds that the addition of small per-

centages of copper reduces the corrosion rate very markedly, as compared with that of ordinary iron, under conditions where the product is alternately wet and dry. For example, after thirty-two months' exposure to the atmosphere the sheets containing 0.01 per cent Cu lost 33 oz. per sq.ft., those with 0.018 per cent Cu lost 23 oz., and those with 0.2 per cent Cu lost but 6 oz. Buck finds that after some months exposure a firmly adherent film is formed on copper-steel which cannot readily be removed with a wire brush. Some idea of the thickness of this film was obtained by first weighing, then scratch-brushing the samples and weighing again, and then removing the tenacious scale with an ammoniacal solution of ammonium citrate and weighing once more. In this manner very concordant results were obtained indicating that after eight months' exposure the closely adherent scale weighed 2.3 to 2.4 oz. per sq.ft. and at the end of thirty-two months 2.8 to 2.9 oz. The closely adherent scale can therefore be figured to be 0.12 to 0.15 mm. thick. Buck also found that steel carrying 0.03 per cent S requires at least 0.07 per cent Cu, and steel carrying 0.055 per cent S 0.12 per cent Cu. He concludes that the inhibition of corrosion through the addition of copper may be accounted for in two or more ways. The harmful influence of sulphur on corrosion is in some manner controlled by the copper; furthermore, the dense film which is formed on copper steels is a real and efficient protector of the underlying metal.

E. A. Richardson of Cleveland pointed out that Buck's curves show that the dominant factor in the decreased corrosion of copper-bearing steels is the composition of the metal itself and that the adherence of the rust coating is a secondary factor. William H. Walker of Boston referred to tests that indicated that copper-steel produces its own protective covering only when the oxygen concentration is high. When the amount of oxygen is limited, as when the structure is immersed in water, corrosion proceeds comparatively rapidly. L. T. Richardson of New York concludes from Buck's tests that the rate of corrosion appears to be influenced mainly by the composition of the metal surface exposed.

O. W. Storey of Madison, Wis., made a careful study of the report of the American Society for Testing Materials and finds that copper-steels made by the acid process which were high in phosphorus were much more resistant to corrosion than low-phosphorus copper-steels made by the basic process. This finding checks up with conclusions drawn by Buck some time ago. This phase of the subject is, however, not definitely solved. It may be that the addition of phosphorus to some of the pure irons or low-phosphorus basic open-hearth steels will have a favorable influence and make them as resistant to corrosion as the acid open-hearth or bessemer copper-steels are at present. The sheets that Buck reported upon were basic open-hearth of an unpublished phosphorus content.

¹Observations on the Mechanism of the Increased Corrosion Resistance of Steel and Iron Due to Small Copper Contents.

E. A. and L. T. Richardson² investigated samples of iron that have resisted atmospheric corrosion for upward of thirty years. Those samples containing 0.1 per cent copper or more were in good condition, whereas those that were free from copper or contained but traces were in poor condition. This confirms Storey's results on tests of eighty different fence wires. The wires which were in better shape always contained Cu. A. S. Cushman of Washington maintained that the evidence was not complete to attribute the resistance to corrosion of the fence wires to the presence of copper; there are other factors that must be taken into account.

T. S. Fuller³ of Schenectady described simple tests which closely correspond to atmospheric tests but can be readily carried out in the laboratory. Progressive placing of drops of water on the same spot of a sheet of metal and allowing each drop to evaporate before adding the next one showed that the first drop was much more "corrosive" than subsequent drops, indicating that a partial immunity is built up. The activity of the first drop is three times that of the second drop. Ordinary cold-rolled iron corroded more than

conditions, which are not comparable to most of the conditions of service. They believe that the only reliable test is the immersion test. Samples cut from three sheets of the following composition were tested:

Sheet	C	Mn	S	P	Cu	As
K	0.04	0.29	0.038	0.077	0.20	0.015
C	0.011	0.032	0.039	0.055	0.251	0.102
A	0.011	0.015	0.038	0.006	0.038	0.012

The K and C samples corroded rapidly, as compared with A samples, in solutions of bichromate, aluminum sulphate, aluminum chloride, cold hydrochloric acid and dilute nitric acid; on the other hand, in sulphuric acid and in concentrated nitric acid the samples K and C with the higher copper content stood up better. In general, Cushman and Coggeshall find that "wherever and whenever copper as an alloying constituent in steel does not show itself to be inert, it shows itself to be deleterious and in some cases dangerously so." Buck admits that the protective surface film can be removed by electrolytes; he used ammoniacal solutions of ammonium citrate. The fact, however, remains that copper-bearing iron and steel are more resistant to

FIG. 1. CORROSION OF IRON AND STEEL WITH AND WITHOUT COPPER, HELD TOGETHER IN VARIOUS COMBINATIONS BY COPPER RIVETS

iron containing 0.29 per cent Cu, and this in turn corroded more than iron containing 2.57 per cent Cu. According to Fuller's test one can determine relative resistance to corrosion in a day in the laboratory as well as with a year's test in the atmosphere. Fuller agrees with Storey and others that there are very likely other metals or elements besides copper that retard corrosion when added to steel in small quantities.

COPPER-STEELS EXPOSED TO PRODUCTS OF COMBUSTION

Storey suspended samples of steel, with and without copper, in the stove flues in households in different sections of the country. He found that steels with about 1 per cent copper are three times as resistant to the combined action of the products of combustion and the alternate heating and cooling of a range as steels with but 0.06 per cent copper.⁴ Aupperle does not agree with these tests, and finds that pure iron lasts eight times as long as copper-steel in hot flues.

COPPER-STEEL IN WATER AND IN ELECTROLYTES

A. S. Cushman and G. W. Coggeshall⁵ look upon the atmospheric test as covering only a special set of con-

atmospheric corrosion than copper-free iron or steel.

Aupperle and Strickland⁶ likewise conducted immersion tests in a solution containing 0.7 per cent sulphuric acid, 2 per cent ferrous sulphate and 0.15 per cent ferric sulphate. The solution was kept in circulation by means of an airlift. The test lasted sixty days: Commercially pure iron with but 0.018 per cent Cu lost 0.380 oz. per sq.ft., as against 0.430 oz. for 0.304 per cent copper-iron and 1.213 oz. for 0.340 per cent copper-steel. Samples of copper-steel that had withstood atmospheric corrosion for a number of years subsequently lost several times as much weight in the immersion test as did the pure iron samples which failed first in the atmospheric test. Furthermore, when dissimilar metals are used for the construction of tanks, boilers, pipes, etc., and when such metals are in contact with water containing ferrous sulphate and sulphuric acid, the iron or steel containing the most copper will be the first to fail. Such tests are illustrated in Fig. 1.

Oliver P. Storey and H. C. Knapp of Madison, Wis., took samples of ordinary sheet iron, 0.25 per cent copper-steel and commercially pure iron and immersed them in dilute sulphuric acid.⁷ The tests were then repeated except that 0.1 to 2.5 g. of copper was added

⁷The Effect of Copper and Silver Salts on the Corrosion of Iron by Acids.

to the electrolyte as copper sulphate. It was found that corrosion was from three to five times as severe in the presence of the copper salt irrespective of the copper content of the sample.

In comparing the immersion tests of Cushman, Aupperle and others on copper-iron and copper-steel with the atmospheric corrosion tests of Buck, Fink suggested that the difference between the two tests was largely one in degree. By the acid immersion test we bring about results which may take very many years to obtain by mere exposure of the samples to the weather. This view is supported by Buck's findings as recorded

FIG. 2. LOSSES ON SPECIMENS CLEANED WITH CITRATE

in Fig. 2. The addition of copper merely reduces the rate of corrosion; throughout the life of the sheet, the rate is practically constant. Thus, for example, sheet iron with but 0.01 per cent Cu will corrode at the rate of 1 oz. per month per sq.ft. of metal exposed as compared with one-fifth of an ounce per month for sheet iron containing 0.20 per cent Cu.

THE FERROXYL TEST

This test, which has been repeatedly described in the literature, and which consists of imbedding small steel or iron samples in gelatine saturated with ferricyanide and phenolphthaline, is decidedly simple and very instructive. Cushman reproduced on the screen a series of very interesting tests made on iron nails. A photograph of one of these tests is herewith reproduced. (Fig. 3.) This is unusually attractive on account of the distinct lines (dark blue in the original) which

FIG. 3. FERROXYL TEST. A. S. CUSHMAN

have all the appearance of "magnetic lines of force." J. W. Richards and Cushman were of the opinion that these lines are due to electrolytic action; W. C. Moore, however, maintained that the lines were merely due to diffusion. The point is not definitely decided and further investigation would appear well worth while.

PRACTICAL MEANS OF PREVENTING CORROSION OF BOILER TUBES AND HOT WATER PIPES

F. N. Speller, of Pittsburgh, finds that in the case of boiler tube and hot water pipe corrosion, the destructive element is oxygen.⁸

Besides oxygen, carbon dioxide may be the direct cause of boiler tube corrosion.⁹ Worth found that the cause of rapid corrosion of a boiler at a Keport plant was attributable to the presence of soluble bicarbonate of iron in the supply water. Upon heating, large quantities of CO₂ were evolved. The water was then treated by being kept at the boiling point for eight hours in a preheater, where the carbonic gas was liberated and a sludge of ferric hydroxide precipitated. The corrosion trouble then ceased.

PAINT AS A NON-CORROSIVE FILM FOR IRON AND STEEL

H. A. Gardner¹⁰ recommends that paints for priming steel should preferably be made of a substantial amount of one or more basic or chromate pigments, and that these paints should be covered with water-resisting finishing coats of carbon or iron oxide. Zinc and aluminum bronzing powders applied direct to steel surfaces possess much greater rust-preventing properties than the powders of other metals. A high-grade exterior spar varnish should be used for suspending the powders.

CORROSION OF BURIED LEAD CABLES

The results of E. R. Shepard's investigation on lead cables¹¹ agree in general with those of McCollum and Ahlborn¹² of the Bureau of Standards. Shepard extended some of these tests at the bureau. The relation between the moisture content of the earth and the coefficient of corrosion¹³ is shown in Fig. 4. Curves in Fig. 5 show the coefficient of corrosion for different

percentages of the total time the lead test plates were anodic. In other words, with periodically reversed currents the coefficient of corrosion based on the anodic current decreases rapidly with time. With continuous current, the coefficient of corrosion in both tap water and earth decreases with an increase in current density. In reference to the corrosion of lead in sulphuric acid, Bancroft felt that although lead peroxide must go into solution in order that the battery function, on the other hand, the same oxide protects the lead of the grid: One is a loose packing, the other an adherent film.

THE CORROSION OF ALLOYS

One of the most interesting and instructive papers of the symposium was that of H. S. Rawdon on "Some Types of Non-Ferrous Corrosion." The author discussed the structural changes caused by corrosion of non-ferrous metals as belonging to four distinct types—namely (a) Selective attack of certain constituents. (b) Inter-crystalline brittleness. (c) Internal oxidation. (d) Simultaneous action of stress and corrosion. As examples of each type the following are given: Type *a*—Brass (60 per cent Cu, 40 per cent Zn) was exposed to sea water for seven years. The α constituent (65 per cent Cu) was untouched, while the β constituent (50 per cent Cu) was corroded by a leaching

out of the Zn, as shown in Fig. 6. Type *b*—Cable sheath of Pb exposed underground became brittle due to the destruction of the intercrystalline material (usually non-miscible impurities such as Fe, Cu, Ni, Zn or miscible eutectic-forming elements as Sn or Sb). This type of corrosion can be induced by immersion in lead-acetate solution. Type *c*—Boiler safety plugs of Sn deteriorated by change of metal to infusible oxide under influence of moist heat. (See Fig. 7.) The same type of change is found with Al-Zn (15 per cent) alloys. In this case moist heat causes the oxidation and swelling of the eutectic matrix. Type *d*—Brass and lead under combined stress and corrosion will fail far below normal stress. This is due to selective corrosion of the β constituent in the former, and to inter-crystalline brittleness in the latter.

The foregoing cases of non-ferrous corrosion have been chosen as types to illustrate a few of the many forms in which failure by corrosion may occur.

FIG. 6. MICROSTRUCTURE OF MUNTZ METAL SHEET. X 500

a. Microstructure of a Muntz metal sheet showing the two constituents, α and β . Etching reagent, ammonium hydroxide and hydrogen peroxide.

b. Microstructure of corroded sheet of Muntz metal, after seven years' exposure in sea water; the β constituent has disintegrated into a weak pulverulent material resembling copper. Etched with ammonium hydroxide and oxidized in the air.

Although the four illustrations have been described as distinct types for convenience, it is quite evident that they are distinct types only so far as appearance is concerned. Fundamentally, they are all very similar.

The increased corrosion due to internal strains or flaws as in the case of the lead pipe will probably account for the failure of the cast iron acid egg which C. L. Fineman reported had been in service for six months for handling mixed nitration acids when it suddenly cracked.

The principles of alloying to resist corrosion appear to Oliver P. Watts comparatively simple. He believes that to increase the resistance to corrosion of any metal there should be alloyed with it another metal which is more resistant to corrosion and which forms a solid solution with the metal whose resistance to corrosion it is desired to enhance. Fink pointed out that the subject was much more intricate than Watts supposed. E. A. Richardson also took exception to Watts' broad generalities. He quoted the case of alloying silicon and iron. Although the two elements form a solid solution and although silicon is much more resistant to corrosion than iron, yet when alloyed with pure iron (say up to 4.5 per cent) resistance of the iron to atmospheric corrosion is materially reduced. The same is true of arsenic and tin when alloyed with iron. John F. Thom-

FIG. 5. VARIATION OF ANODIC CORROSION WITH PERCENTAGE OF TOTAL TIME PLATES ARE ANODIC. ON 20 MIN. PERIOD, 0.5 M.A. PER SQ.CM. TIME 100 HR. SATURATED EARTH AND TAP WATER

son shows conclusively in a paper on "A Practical Aspect of the Corrosion Problem" that there are very many factors involved in the selection of an alloy to resist corrosion. Although corrosion resistance is always a necessary factor, it is quite frequently not the determining one which governs practical serviceability. Not only must the chemical factors be taken into account, but also usually the mechanical properties, and very often too the electrical. There is every indication that nickel alloys will be used to much greater extent hereafter.

In closing the symposium, Colin G. Fink summarized the more important points brought out during the two days' discussion as follows: (1) Iron or steel containing about $\frac{1}{4}$ per cent copper will withstand atmospheric corrosion better than iron or steel without copper. (2) Iron or steel containing about $\frac{1}{4}$ per cent copper, when completely immersed in ordinary tap water or in

a. Longitudinal section of a "safety" plug. The filling of tin was changed almost completely by service conditions into a hard refractory mass of tin oxide; a few globules of tin may still be seen in the interior. $\times 1$.

b. Portion of a after polishing the surface. The white areas are globules of tin which fused when the plug became overheated. $\times 2$.

FIG. 7. STRUCTURE OF CORRODED SAFETY BOILER PLUGS

acidulated water, does not resist corrosion as well as pure iron. (3) In boiler practice and in hot water systems (closed systems) the presence of oxygen greatly accelerates corrosion; the removal of this oxygen practically eliminates corrosion. (4) Carbon dioxide in boiler water, together with soluble iron, causes corrosion, and the removal of the CO_2 practically eliminates corrosion. (5) Other elements, such as Cr, Si, Ni, Co, etc., added to iron in well-defined amounts tend to reduce corrosion, but detailed investigations have as yet not been reported. (6) A satisfactory co-ordination of alloy corrosion research needed but lacking.

Fink also made the following suggestions for future study and research: (1) A thorough investigation of the surface film involving careful determinations of the chemical and of the physical properties of this film—e.g., chemical composition, porosity, tenacity, coefficient of adhesion, coefficient of expansion, etc.—as compared with those of the underlying metal. (2) A careful study of the microstructure of the metal near the surface and a similar study of the metal directly underneath the surface film. (3) The effect of chemical and mechanical treatment on the surface film and the underlying metal. (4) A more complete micrographic investigation of the surface changes of metals during the process of corrosion. (5) A better classification of corrosion phenomena—for example, we must define the limits of moisture and salts in air in which the tests were made. (6) A standard of measure of corrosion.

Dye Imports

BY C. R. DE LONG

The following statistics on imports of dyes during 1920 were presented to the Dye Division of the American Chemical Society at the meeting in Rochester April 28. They were prepared by Dr. C. R. de Long, chemist for the U. S. Tariff Commission:

	Lb.
Total imports of coal-tar dyes during calendar years	
1920	3,700,000
Vat dyes other than indigo	855,000
Indanthrene blue GCD	150,000
or 18 per cent of total for this class.	
Indanthrene yellow R & G, about 10 per cent total	
Indanthrene black BB, about 10 per cent total	
Bromindigo	34,000
Ciba scarlet	25,000
Hydron blue	20,000
Ciba violet B	18,000
Mordant and chrome dyes	840,000
Anthracene blue WR	114,000
or 13 per cent of total for this class.	
Alizarine	73,000
or 9 per cent of total.	
Brilliant delphine blue BS	29,000
Eriochrome blue black B	20,000
Omega brown PB	11,000
Acid dyes	765,000
Wool green S	127,000
or 16 per cent of total for this class.	
Patent blue and patent	
Blue A	86,000
or 12 per cent of total.	
Xylene light yellow 2G and R, about 10 per cent total	
Tartrazine	57,000
Quinoline	35,000
Xylene light blue VS	26,000
Acid violet 4BN	22,000
Direct Dye	595,000
Zambesi black	about 40,000
or 7 per cent	
Trisulfon brown B and MB	about 40,000
or 7 per cent	
Trisulfon brown GG	about 40,000
or 7 per cent	
Chloramine brilliant	about 23,000
or 4 per cent	
red 8B	about 23,000
or 4 per cent	
Pyracol orange G	about 23,000
or 4 per cent	
Heligoland black	about 23,000
or 4 per cent	
Sulphur dyes	255,000
Thionol red brown	38,000
or 15 per cent	
Thionol green DY	24,000
or 10 per cent	
Basic dyes	200,000
Auramine	85,000
or 45 per cent	
Phosphine	20,000
or 10 per cent	
Indigo	171,000

The above figures are approximate, and under each class only the more important dyes have been listed.

Foreign Commerce of Belgium

According to the statistics just published by the Belgian Minister of Finance it appears that the commerce of Belgium in 1920 amounted to 22,495,041 metric tons (1 metric ton = 2,204.6 lb.), of which 11,946,448 tons was imports and 10,548,593 tons exports. This commerce was valued at 19,879,549,000 f. (\$1,443,161,451), of which 11,171,467,000 f. (\$810,995,789) was imports and 8,708,082,000 f. (\$632,165,670) exports. The imports for 1920 exceeded those of 1919 by 5,948,420,000 f. and the exports by 6,419,246,000 f.

Beet-Sugar Project in China

A newly organized Chinese concern named the Pui Chih-Tang Kungsu expects to establish a beet-sugar factory near Huangtaichiao, states an issue of the *Trans-Pacific*. The company's capital amounts to \$5,000,000 and is entirely Chinese owned. All machinery and equipment will be imported from America. The capacity of the plant will be about 6,000 tons of sugar a year.

Calculation of Percentage Removal of a Constituent From a Mixture

BY W. B. VANARSDDEL

A VERY common problem in laboratory and plant work is the calculation of the percentage removal of one constituent from a mixture, given the original and final percentages of that constituent in the mixture. Among the instances which might be cited are the following: Recovery of a gas or vapor from accompanying inert gases by passage through an absorption tower; calculation of weight of water to be evaporated from unit weight of a wet material to reduce the moisture content from one specified percentage to another; determination of the proportion of resin or fat recovered by treatment of an oily or resinous material with a solvent. A number of dilution or evaporation charts have been proposed [cf., for instance, Deming, *J. Ind. Eng. Chem.*, vol. 8, p. 265 (1916)], and with slight modifications these might apply to such problems as the second one above; but there seems to be no published work serving just the purpose of the present chart.

It is very easily shown that if a is the original and b the final percentage of a constituent M in a mixture, the percentage of removal of M ,

$$R = \frac{10^4 (a - b)}{a(100 - b)} \quad (1)$$

This equation can be "graphed" most easily by means of an alignment chart, but it is the experience of the writer that persons unfamiliar with the principle

of the alignment chart use it with hesitancy and are disinclined to use the auxiliary straight-edge required; a network of curves or straight lines, on the other hand, while more difficult to draw accurately, seems to be used with facility. If drawn to a sufficiently large scale, interpolation offers no particular difficulty; in cases where the range of the variables is limited, only a portion of the network need be drawn, and magnification of the units permits greater accuracy of interpolation. In the present case a network of straight lines is set up, covering the whole range from 0 to 100 per cent for each percentage; the accuracy is therefore low when both a and b are very near 0 or 100 per cent. The triangle was made equilateral merely to increase the average angle of intersection of index lines.

It may not be out of place to remark that in the case of a mixture of gases, even if the temperature changes a and b may be expressed in volume-per cent, and R will still represent percentage removal by weight. This fact is dependent upon the mixture's behaving according to the simple gas laws and therefore, strictly speaking, excludes vapor mixtures. An example for calculation

may be taken from the simple case of a 40 per cent original component reduced to a final content of 25 per cent. The intersection of these two lines determines the percentage of removal—50. With any two lines stated, the other is determined, so that solution to all such cases is simple. Where greater accuracy is desired, a larger chart with subdivisions should be drawn.

Research Department,
Berlin, N. H.

Behavior of Copper in Molybdenum Ores

Brief Notes on Methods by Which Copper May Be Separated From Molybdenum Ores or Concentrates Previous to Reduction—Precautions to Be Taken in the Analysis for Copper in the Presence of Molybdenum

By J. P. BONARDI AND MAX SHAPIRO

MOLYBDENUM ores are found that contain copper minerals, in some cases in commercial quantities, the presence of which is objectionable because they are usually carried into the molybdenum concentrates. If these concentrates are to be used for making ferro-alloys or steels they are by some purchasers seriously objected to and penalized, depending upon the amount of copper present. Previous to 1917 copper in molybdenum concentrates was particularly undesirable and its presence in excess of 1 per cent, even in high-grade molybdenite concentrates, was usually sufficient to render the material unmarketable. Some dealers did, however, accept concentrates containing more than 1 per cent copper, but when 4 or 5 per cent copper was present the penalties exacted were such as to be prohibitive. Since then various new methods of ore dressing have been tried out with varying degrees of success, which have to a great measure eliminated the copper content in molybdenum concentrates, so that at the present time the copper content can be kept around 0.5 per cent, and usually less, depending upon the relative proportions in the ore.

Very little exact information is at present available as to the copper limitation placed on molybdenum concentrates; it is generally stated as between 0.2 and 0.5 per cent, although some dealers have taken molybdenite concentrates carrying any amount of copper, since their process of roasting and extracting the molybdenum renders the copper insoluble in the residue.

GRAVITY CONCENTRATION

In treating wulfenite ores it has been found by some workers that the vanner proved an excellent machine for removing the associated oxide copper minerals from the wulfenite. Although it was known that wulfenite is somewhat friable it was found that the very fine wulfenite minerals of an unclassified feed would, when submitted to a vanner, readily attach themselves to the moving surface and be retained. This is because the mineral is readily wetted; while the gangue particles and copper minerals, being of lower specific gravity, and not so easily wetted, would be carried off by the stream of water, even though larger in size.

However, in the concentration of molybdenite by the oil flotation process sulphide minerals of copper, usually in the form of chalcopyrite, are likewise carried over with the molybdenite froth and are then found in a more concentrated state than originally present in the ore. Differential flotation, however, bids fair to eliminate this trouble, and very many successful experiments to this end have been made at the Golden Station of the United States Bureau of Mines. Horton,¹ in describing the deportment of chalcopyrite in the concentration of molybdenite, states that by both elec-

trostatic and flotation methods they are concentrated together. The removal of pyrite and chalcopyrite from molybdenite is accomplished to a great extent by giving the ore or concentrates a careful roast. In this way the larger part of the pyrite and chalcopyrite are rendered magnetic and may be removed by means of a magnetic separator, or, through the formation of a coating of oxide on the surface of each particle, the pyrite and chalcopyrite in the ore are readily wetted and sink if the material is subjected to flotation. It is cheaper and more effective as regards ultimate recovery of molybdenite to remove the other sulphides after concentration rather than before. The danger in roasting molybdenite ores is that if the surface of the molybdenite becomes oxidized, its complete recovery by ordinary oil flotation processes will be doubtful.

Thornhill (U. S. Pat. 1,338,264) effects separation of molybdenite from other mineral sulphides by treating pulp with oil, whereby molybdenite appears to "coagulate" in preference to other minerals and can be separated by fine screening.

FLOTATION BY SURFACE TENSION

Another method suggested is that of oxidizing the surfaces of chalcopyrite at ordinary temperatures and later submitting the material to the Wood's surface-tension machine, whereby the chalcopyrite sinks while the molybdenite flakes are floated on the surface and are recovered. It is known that the ordinary type of wet concentrating table will to a certain degree effect a separation, due to the flakiness of the molybdenite and to the fact that it is not readily wetted, which usually makes it the tailing product.

In case the ratio of copper to molybdenum is relatively large it is doubted whether any of the processes suggested above will reduce the copper content much below 1 per cent. The application of differential flotation may in the future be able effectively to separate molybdenite from chalcopyrite within the limits that are allowed, and very likely at the same time produce two marketable products—a copper and a molybdenum concentrate. This would then eliminate the costly roasting processes or hydrometallurgical processes now being attempted to solve this problem.

REACTIONS BETWEEN MOLYBDENUM AND IODINE

The accurate determination of copper in copper-molybdenum ores that have come to this station for testing by flotation processes and for the analysis of the products made therefrom is of importance to the metallurgist. After several trials had been made to determine copper by the ordinary methods in such products it was soon found that the presence of molybdenum was a serious hindrance. The standard iodide method of determining copper cannot be used without previously separating the molybdenum from the copper or vice

¹Published by permission of the Director, Bureau of Mines.

¹Horton, F. W., "Molybdenum: Its Ores and Their Concentration," U. S. Bureau of Mines Bull. 111, 1916, pp. 108-9.

versa, since under the conditions of titrating the liberated iodine by thiosulphate in the ordinary way molybdenum likewise liberates iodine and interferes. Free iodine is liberated when a solution containing molybdic acid (MoO_3) is boiled in the presence of potassium iodide and hydrochloric acid, as follows:

This reaction forms a basis for determining molybdenum. See Scott² and Treadwell and Hall.³

INCOMPLETE PRECIPITATION ON ALUMINUM

In the ordinary standard copper-iodide method the bulk of the copper is previously precipitated by aluminum or zinc, which is followed by H_2S water to precipitate the small amount of copper which usually is difficult to precipitate by the previous treatment. It has been found that in the presence of molybdenum, zinc or aluminum in any form—sheet, granulated or powdered—will not completely precipitate the copper. H_2S water as used in the ordinary method for copper cannot be used for carrying down the remaining copper in solution, since this will likewise precipitate MoS_3 along with the copper sulphide. After making several attempts to precipitate the copper completely by zinc and aluminum in various forms without the use of H_2S and under different working conditions it was finally given up as being practically impossible, since it always led to the same erratic results. The chief difficulty with using aluminum strips or sheets is that the precipitated copper adheres so firmly to the metal when molybdenum is present in solution that the deposition of copper stops. Granulated zinc, however, gave the best results, but requires the complete solution of several grams of zinc, which leaves the copper in a very finely divided condition, and which is very difficult to filter off and wash without losing some of the precipitate in the filtrate, due either to its colloidal nature or to oxidation. No H_2S wash water could be used on account of the danger of precipitating MoS_3 .

The use of sodium hydroxide for precipitating out the copper along with the iron-group metals was next tried out and proved satisfactory. By boiling, the copper hydroxide will be rendered insoluble, while the molybdenum passes into the filtrate. The precipitate must then be redissolved and reprecipitated to get rid of the trace of molybdenum remaining in the precipitate. The precipitate is next dissolved in dilute H_2SO_4 , and the copper thrown out of solution by the ordinary procedure, using aluminum strips, copper filtered off, dissolved and titrated in the usual manner with standard thiosulphate. Although the use of this method is fairly satisfactory for determining copper, the time required for carrying out a determination by performing so many precipitations and filtrations would limit its use in a commercial laboratory where many determinations must be carried out in a single day. Besides these objections, the solution after each addition of the caustic must be boiled vigorously or heated for half an hour to render the copper completely insoluble.

ELECTROLYTIC METHODS

A search through the technical journals revealed the fact that all the methods that had been devised for

determining copper in the presence of molybdenum were modifications of the ordinary electrolytic method.⁴

Very likely for a particular class of material an electrolytic method could be used to advantage, but in commercial work it is probable that by the time all the conditions have been properly made, with all the interfering elements removed, it would have been quicker to carry out a determination by other means. The electrolytic method was therefore not tried out.⁴

After trying out several of the standard wet methods as outlined in various textbooks for determining copper it was found that the thiocyanate method, with a few modifications, gave a complete quantitative separation of copper from molybdenum, while the procedure could be easily and accurately controlled.

MODIFIED THIOCYANATE ANALYSIS

Weigh out 0.5 to 5.0 g. of the finely pulverized material, depending upon the grade of sample, copper content not to exceed 0.20 g., into a 250-c.c. beaker or Erlenmeyer flask. Add 10 to 15 c.c. of HNO_3 and heat until the brown fumes are gone. This is the most effective manner of decomposing the sulphides present in an ore. Carefully add 5 to 10 c.c. of HCl and heat about twenty minutes, or until the ore is carried down to near dryness. On straight sulphide material the use of HCl can be dispensed with. Cool, dilute and add 10 to 15 c.c. of dilute sulphuric acid (1:1) and then if necessary just enough additional water to dissolve all the soluble salts in the residue or precipitate formed. If this is not done some nitrates are liable to cake on the bottom of the beaker or flask, or be trapped in the insoluble matter and may not be fully decomposed by the sulphuric acid. The presence of nitrates hinders the precipitation of copper. Evaporate the mixed acid solution down to copious fumes of H_2SO_4 , cool, dilute with a little water, heat to dissolve soluble salts and if much residue is present, filter off, catching the filtrate in a 600-c.c. beaker, and wash residue at least five times with hot water. The final volume will be approximately 250 c.c. This filtrate (or diluted solution from an acid treatment which requires no filtering) is now ready for precipitating out the copper by means of a solution of ammonium thiocyanate, while the molybdenum remains in solution. To the above acid solution add NH_4OH until the solution becomes slightly alkaline, indicated by an iron precipitate, then add dilute H_2SO_4 (1:1) until the solution is made acid and contains about 2 c.c. of free acid in excess.

Next add 2 to 3 g. of anhydrous Na_2SO_3 to reduce the copper. At the same time the sulphite may reduce some of the molybdenum, giving a blue solution, depending upon the concentration of acid. If too much Na_2SO_3

⁴Hoepfner, W., and Bender, O., "Determination of Molybdenum in the Presence of Copper," *Chem. Zeit. Jahrg.*, vol. 42, 1918, p. 315, pp. 301-2; also *Chem. Abs.*, vol. 12, 1918, p. 2293. Treadwell, W. D., "Electro-Analytical Separation of Copper From Tungsten and Molybdenum," *Z. Elektrochem.*, vol. 19, pp. 219-21; see *Chem. Abs.*, vol. 7, 1913, p. 2170. McCay, L. W., and Furman, N. H., "Use of Hydrofluoric Acid in the Separation of Some Heavy Metals From Tin, Antimony, Tungsten and Molybdenum by Means of the Electric Current," *J. Am. Chem. Soc.*, vol. 38, 1916, pp. 640-52.

⁵In describing the electrolytic copper assay in the presence of molybdenum, Hawley states: "In the electrolytic method for assaying copper, molybdenum acts like arsenic and antimony, part precipitating and part remaining in solution. When too much is not present, the addition of a small amount of any chloride will prevent its precipitation. One mg. of sodium chloride will prevent about 6 mg. of molybdenum from precipitating. This small amount of chloride is insufficient to injure the copper deposit. When molybdenum precipitates, the color varies with the amount present. With very little, the color is a chocolate brown that rarely extends to the edge of the cathode. With still more, an iridescent steel-blue color is evident that approaches black as the quantity is increased." (*Eng. & Min. Jour.*, vol. 110, July 24, 1920, p. 162.)

²Scott, W. W., "Standard Methods of Chemical Analysis," 2nd ed., 1917, pp. 275-282.

³Treadwell and Hall, "Analytical Chemistry," vol. 2, 3d ed., 1917, p. 666.

should be added, indicated by a precipitate, add a little more of the dilute acid solution. Heat nearly to boiling and add 10 to 25 c.c. of a solution of NH_4CNS or KCNS containing 2 g. per 10 c.c. An excess of this reagent does no harm. The copper will be precipitated as cuprous sulphocyanate, CuCNS . Heat for a few minutes longer, or until the precipitate has coagulated and settled. Filter through a good grade of qualitative paper and wash with hot water until the blue color on the filter paper, due to reduced molybdenum, has been leached out. Usually five to eight washings will be sufficient. Redissolve the precipitate back into the original beaker by puncturing the filter paper and washing the content into the beaker with a small stream of hot water. Then pour onto the filter 10 c.c. of warm 1:1 nitric acid, which will dissolve the adhering bit of precipitate on the paper and the washed down precipitate held in the beaker. If the precipitate is small it can be easily and readily dissolved with a little hot 1:1 nitric acid poured directly upon the filter. Brown oxides of nitrogen are given off by the reaction.

The solution is then placed on the hot-plate and evaporated down practically to dryness. This requires but a very short time and more than balances the time spent in the straight iodide method, where the nitric acid solution of copper containing some bromine water must be boiled to drive off excess bromine, neutralized with ammonia, again boiled until excess ammonia is driven off, neutralized with acetic acid, cooled to room temperature and titrated with standard thiosulphate. The principal advantage in taking the nitric acid solution of the cuprous thiocyanide nearly to dryness at the start is to expel the cyanide formed and the excess nitric acid, thus eliminating practically all the trouble that usually is experienced in titrating low-grade copper solution with thiosulphate in the presence of ammonium salts. For it has been found that if much ammonium salts is present the precipitate of cuprous iodide forms with difficulty and the end point is then very uncertain and unreliable, it being rather doubtful when the blue color will not again reappear through the formation of a little more iodine caused by the slowness of the reaction, due to excessive amounts of ammonium salts present. If accurately performed the blue color should not reappear upon standing from three to five minutes.

After the copper solution has been evaporated as described it is cooled. In case it was carried to complete dryness add two or three drops of concentrated nitric acid, next add 50 c.c. warm water, then a few drops of concentrated ammonia until the solution becomes clear, giving the characteristic deep blue color; avoid using an excess. Usually five to ten drops will neutralize all the nitric acid present at this stage, and at the same time be sufficient to dissolve the first precipitate of copper hydroxide. Next add 5 to 10 c.c. acetic acid, cool to room temperature, add sufficient amount of potassium iodide solution and titrate the brown solution of liberated iodine containing cuprous iodide with standard sodium thiosulphate until the blue color of a starch indicator disappears. It is best to titrate without starch in solution until the brown tinge has become faint and then add sufficient starch solution to produce a marked blue color. Titrate cautiously until the blue color is entirely removed by a single drop. The c.c. of thiosulphate multiplied by the copper value

of the reagent gives the weight of copper in the sample from which the percentage is calculated.*

REACTIONS

Reactions involved are:

According to the above equation $2\text{Cu} = 4\text{KI}$, or 0.2 g. of copper requires about 1.05 g. KI, and 100 per cent excess over this theoretical quantity is always added before titration. Prepare a solution containing 50 g. KI in 100 c.c. Five to 6 c.c. of this solution will take care of any high-grade samples encountered. For low-grade samples 2 c.c. will be sufficient.

INTERFERENCES

Nitrogen oxides, ferric ions, trivalent arsenic and trivalent antimony must be absent, as they will either absorb or liberate iodine. Pentavalent arsenic and antimony do no harm; hence, if these are suspected in the ore, 5 c.c. of bromine water should be used along with the nitric acid, after dissolving the cuprous thiocyanate, care being taken that the excess is boiled off by evaporating nearly to dryness as recommended for the presence of excess nitric acid. The presence of 3 g. of tartaric acid is recommended by Lord and Demorest⁷ to keep arsenic, antimony and bismuth in solution when the copper is precipitated with thiocyanate. The writers have never resorted to the use of tartaric acid, but prefer the use of bromine in ores suspected of carrying much arsenic or antimony.

Many tests were made to prove the accuracy of the method with synthetic solutions, but only a few representative ones will be given:

No.	Mo Present	Cu Taken	Cu Found
1	0.0500	0.0238	0.0239
2	0.1000	0.0513	0.0513
3	0.1500	0.0563	0.0564
4	0.2000	0.0109	0.0107
5	0.4000	0.0051	0.0049
6	0.4000	0.2681	0.2676
7	0.4000	0.0023	0.0025
8	0.5000	0.5638	0.5640

The results shown in Table I were obtained on molybdenum-copper ores and products, made from flotation

TABLE I. PERCENTAGE OF COPPER FOUND BY THE THREE METHODS

No.	Per Cent Mo	Per Cent Cu by Thiocyanate Method	Per Cent Cu by Excess Granulated Zinc	Per Cent Cu by Aluminum Strips
1	5.03	1.40-1.42	1.39-1.43	1.01-1.29
2	4.98	15.82-15.78	15.87-15.70	15.60-15.70
3	0.07	0.24-0.24	0.28-0.25	0.29-0.25
4	45.78	0.42-0.43	0.48-0.41	0.46-0.39
5	15.10	5.61-5.70	5.58-5.70	5.27-5.60

experiments, which were analyzed by three methods: The thiocyanate method, as described above; by granulated zinc, and by the regular aluminum precipitation method. Results on the latter method show the radical results to be expected by the use of aluminum.

*The standard solution of sodium thiosulphate is made by dissolving 19.55 g. of pure crystals in 1 liter of distilled water. Lord and Demorest recommend adding 1 g. of NaOH to preserve the solution. The solution is next standardized by weighing out 0.2 g. of pure copper wire or foil, dissolve in 10 c.c. of 1:1 HNO_3 , carried to near dryness and treated as outlined in the method above. One c.c. of the thiosulphate will correspond to about 0.005 g. of copper.

⁷Lord and Demorest, "Metallurgical Analysis," 1916, p. 206.

Messrs. Anderson and Prest of the Seattle Station, Bureau of Mines, have been able to use the following alternate method with good results on many ores.

PERMANGANATE METHOD FOR COPPER

The cupro sulpho-cyanate precipitate is dissolved in hot 10 per cent NaOH, copper hydroxide filtered off, and the NaCNS in the filtrate titrated with KMnO_4 , using ferric chloride on a spot plate as indicator of consumption of NaCNS. The solution is then made acid with H_2SO_4 and the liberated HCNS titrated until the usual permanganate end color is reached.

Some uncertainty exists as to the factor which will convert the iron value of the permanganate to the copper value. To fix this point, 0.20 g. of copper is dissolved in HNO_3 and carried through exactly as a regular determination.

Scott recommends that the precipitated sulpho-cyanate be weighed in a Gooch crucible after drying at 100 deg. C. The compound multiplied by 0.5226 gives the equivalent metallic copper. Or the dried precipitate may be burned with sulphur to Cu_2S . The factor is then 0.7986. In Scott's view, copper is separated as sulpho-cyanate from a great many elements without interference, except from silver, tellurium and selenium.

Synopsis of Recent Chemical & Metallurgical Literature

Superficial Burning of Low-Carbon Steel—In a paper read before the West of Scotland Iron and Steel Institute, James Mitchell refers to a type of defect which frequently arises in practice, which for want of a better term may be described as superficial burning. In such cases the metal is destroyed on the surface, presumably through the oxidizing effect of the flame employed in heating. It seems probable that this oxidation arises from the action of the surface scale formed on the piece. Microscopically it becomes apparent through decarburization of the superficial layers. After such treatment the failure of the metal is common, the reason being that the surface fissures caused through over-oxidation serve as starting points for the propagation of cracks throughout the steel. It may be argued that when fluxes are used on the metal such conditions do not readily arise. Mr. Mitchell's experience, however, has been that under such conditions fluxes afford a very poor protection, as the surface cinder formed is itself of a very oxidizing nature.

Wheel-Burnt Rails.—A derailment on the Baltimore & Ohio R.R. at Glenwood, W. Va., supposed to be due to a "wheel-burnt" rail—that is, a rail which had been intensely heated momentarily and locally by slipping wheels—led to a study and report of this type of damage by J. E. Howard, engineer-physicist of the Interstate Commerce Commission. Fragments of the broken rail (Fig. 1), the appearance of the rail head both before and after pickling (Figs. 2 and 3), and microscopic examination (Fig. 4) show that the rail—which was a 75-lb. A. S. C. E. section in service for nine years—contained many fractures having origin at the hardened upper surface of the rail.

In his investigations Mr. Howard studied

FIG. 1. TYPICAL END VIEW OF BROKEN FRAGMENTS

FIG. 2. APPEARANCE OF RUNNING SURFACE BEFORE PICKLING

FIG. 3. APPEARANCE OF RUNNING SURFACE AFTER PICKLING

the internal strains and structure in a number of other wheel-burnt rails. He distinguishes between the hardening due to the cold-work attending a rolling load and the thermal hardening due to wheel-slippage. Rail steel embrittled by mechanical hardening commonly displays some residual ductility under wheel stresses, although it is incapable of further flow under tensile stresses. When a longitudinal element of the tread is cut from such a hardened rail it will increase slightly in length, thus showing it to have been under compressive forces. Thermal hardening due to wheel slippage, on the other hand, retains no residual ductility, is incapable of flow under wheel pressures, and the hardened portion is often of insufficient depth to support and distribute the impinging pressures of the wheels. Surface cracks were thus formed in the rail which caused the accident, some of which, under the alternate directions of the tractive forces of engine drivers and the resistance of the train wheels penetrated the head and culminated in rupture.

In order to gain an idea of the stresses which may be

FIG. 4. CRACK THROUGH HARDENED METAL AT SURFACE OF RAIL-HEAD. LONGITUDINAL SECTION. $\times 100$

set up locally by thermal hardening a number of rails were gaged and the changes in lengths noted after various amounts of metal had been cut away, and after various heat-treatments. The mean expansion in 10 in. after channeling the head of the rail and quenching the bar from 1,400 deg F. was 0.0235 in. (gaged length 10 in.). Progressive contraction occurs with increasing temperatures when annealing hardened steel—either hardened by cold-work or by quenching. Thus a hardened spot in a rigid rail head would

be under a compressive stress of 70,500 lb. per sq.in., due to this volume change, while the rest of the rail would have tension induced in it, especially near the top; consequently the effect of local thermal hardening is opposite in direction to that of mechanical hardening. Intense internal strains, induced in rails in this manner, may reasonably be held to have exerted a great influence on the surface cracks exhibited in Fig. 2. However, the approach to rupture in steel in service is not signalized by visible manifestations.

Melting Scrap in Heroult Furnace.—W. E. Cahill describes in *Mining and Scientific Press*, April 16, 1921, p. 535, a 2-ton electric furnace operating at Treadwell, Alaska. With coke at \$50 per ton, and pig iron correspondingly high, it has even become cheaper to make iron castings from this furnace, using hydro-electric power, than from a cupola. Operating "kinks" follow.

"Insulation" is common when starting the furnace on heavy scrap-iron. It often happens that the three electrodes will rest on top of the charge, and no current passes through. A good remedy is to add a few shovelfuls of clean turnings. In extreme cases one can always shovel in some coke, bringing the current over the top of the charge until a steady arc results.

"Iron castings are made about three or four times per week, the usual practice being to pour in the morning. Every afternoon we take off a heat of steel—high-carbon, low-carbon or alloy, depending upon the requirements. The melting of cold steel scrap in a cold furnace gave us considerable trouble at first. The melting starts at the top of the pile directly under the electrodes. The electrodes gradually work their way toward the bottom. As the steel melts it drops down and strikes the cold magnesite hearth and freezes. The electrodes continue their downward path until a pool of molten steel is formed and the melting of the scrap raises the level of the bath. The course is then upward until all the scrap is added. The layer of solid steel on the bottom cannot be melted by keeping the heat on the bath and without overheating or injuring the furnace. The trouble seems to be due to lack of circulation, the hot metal being on the top. This circulation can be insured by the addition of iron ore, which causes the metal to boil and so washes out the layer of frozen metal. Hematite has proved most satisfactory for this purpose, as its action is quick and the effect on the slag is slight. Frequent testing of the bottom with a steel bar is necessary; for, after the steel is free, continued boiling will wash out magnesite, causing slag troubles. This condition is common when using heavy scrap. When proper scrap is available the density of the charge may be so arranged that the electrodes will penetrate near to and will heat the bottom. Great care must be used when the scrap is light, especially if the electrodes are penciled, for the pool of steel formed might not be of sufficient depth to prevent the electrodes from boring into the bottom. It is advisable to know the length of the electrode (that is, the distance from the holder to the furnace bottom), so that if the position becomes dangerous the current may be reduced until it starts to rise.

"Several months ago we had a 'heat' of steel nearly ready to pour, but the power went off and the charge froze in the furnace. A break in the line kept the current off until the next day. By chipping away the slag from under the electrodes we were able to start the circuit. After having the current on the solid chunk for two and a half hours the maximum depth of the pool of molten steel was about 3 in. The furnace was getting very hot, so we started feeding ore. When the carbon content became low pig-iron was added. By alternate addition of ore and pig the steel was finished, and the furnace was poured clean within five hours from the start.

"The charging of the furnace influences the melting. Gates and risers make a good charge for the bottom, giving the proper density; and, being at the bottom, the coating of sand does not interfere with the electric conductivity when starting operations. Light scrap is placed on the top and may be piled a foot or more above the doors. A small piece of coke is placed on top of the scrap directly under each electrode. The coke makes a better contact,

acts as a cushion, and prevents violent surges of current when starting. The former practice of using hand-control for starting has been discontinued, and automatic control is now used. Peak loads seldom exceed 850 kw., whereas the working load is between 500 and 600 kw. After a steady arc is formed, usually about five minutes after starting, lime is shoveled around the electrodes to form the basic slag. Later, as the charge melts, more lime is added. If the scrap melts so as to expose part of the roof to the glare and reflected heat of the arc it is well to work over some of the light top scrap with a bar, so as to shade the arc and prevent unequal heating of the roof."

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

Tribenzyl Phosphate in Celluloid Manufacture.—As a colloid agent for cellulose esters, FRITS E. STOCKELBACH, of New York, recommends tribenzyl phosphate in preference to triphenyl phosphate or tricresyl phosphate. As an example, celluloid may be manufactured by mixing 75 parts of nitrocellulose with 25 parts of tribenzyl phosphate or with 10 parts of tribenzyl phosphate and 15 parts of camphor. Celluloid made in this way does not discolor when exposed to light and is much less flammable than the corresponding product made with camphor alone. (1,370,853; assigned to Commonwealth Chemical Corp.; March 8, 1921.)

Modified Induction Furnace for Melting Scrap.—A furnace body 5 has an interior chamber 6 below which is an opening 7 for the primary core and primary coil. Molten metal within the channel 8 forms the secondary, the arrangement being such that the metal in the furnace is kept in circulation by motor effect in channel 8. The circulation promoted in this manner in the lower part of the bath is quite efficient but, owing to the oil and dirt on the scrap metal and the air in the interstices between the fragments, the upper part of the charge may become insulated and separated from the lower part, forming a bridge or arch over the latter in the nature of a crust which is not heated sufficiently to melt, as above pointed out. In order to overcome this drawback and

the consequent loss of efficiency, auxiliary heating means are provided above the upper surface of the charge constituted by a retort 9 of refractory material or the like formed in or adjacent to the roof portion of the furnace. This retort 9 serves as a combustion chamber and is heated interiorly by an oil burner 10 or the like, which in this instance is arranged exteriorly of the furnace and is adapted to project a jet of flame into the retort through an opening 11. (1,370,632; WALTER R. CLARK, of Bridgeport, Conn., assignor to Bridgeport Brass Co.; March 8, 1921.)

Distilling Column for Ammonia.—In the operation of apparatus in which a volatile content of a liquid, as ammonia, is distilled off by passing steam through the liquid, it sometimes happens that the liquor admitted at the top of the column does not flow freely through it, but accumulates to an abnormal depth in the pans composing it, thus checking up the upward flow of steam and to a greater or less extent blocking the operation. This difficulty is due to the fact that the steam rising from the

boiling liquid in the overflow passages opposes the flow of liquid from the pans to the passages to such an extent that the flow of liquid is checked, thus increasing the depth of liquid in the pans. This increase in the depth of the liquid seal in the pans tends to prevent the steam passing up through the column from following its normal path and to cause it to break through into the overflow passages, thus increasing the original difficulty. An improved apparatus has been designed by GEORGE W. CRUPE of Buffalo, N. Y. Referring to the drawing, A indicates a distillation column, composed of a series of superimposed rings B, B. In each ring is a pan, or faux fond, C, having a central opening c, over which is a hood, or passette, D, whereby steam passing up through the column and through the openings c is forced to pass through the liquor in the pans. Leading from each pan to the pan below is an overflow pipe or passage E, whereby the liquor, overflowing from the several pans, passes downward from pan to pan, through the column. Connected with upper part of each of the overflow pipes E, and preferably with the cover plate e of the overflow pipe, is a vent pipe, F, the upper, or discharge, end of which is above the inlet opening of the overflow pipe and preferably directly under the pan or faux fond of the next succeeding ring above.

In the operation of the device the steam rising from the highly heated liquor in the overflow passage E is free to discharge through the vent pipe F, instead of passing through the inlet opening of the overflow pipe E, and thus is prevented from obstructing the flow of liquor into the overflow pipe.

By this means a more rapid feed of liquor to the column is made possible, and with a uniform feed of liquor a substantially constant depth of liquor is maintained in each pan, thus insuring uniformity and cleanness of operation. (1,372,649; assigned to Semet-Solvay Co.; March 22, 1921.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Dispersoids.—Dispersoids or colloidal suspensions of ores, dyes, paints, graphite, sulphur, cellulose or other materials are obtained by pounding or rubbing the ground substance in a dispersion medium which is a non-conductor or a bad conductor of electricity, the moving surfaces having a velocity of not less than 2,000 m. per minute, and preferably of 1,000 m. per second. Dispersion may be assisted by adding solvent chemical agents, or those which form labile compounds with the dispersion medium without much ionization, or those which assist the formation of compounds between the material to be dispersed and the dispersion medium. A colloidal suspension of sulphur may be made by dispersing flowers of sulphur with water or other medium, with or without the addition of protective colloids such as benzol or carbon bisulphide. Molten sulphur may also be converted into the dispersoid condition, the temperature being gradually lowered during the operation. Sulphur may be refined by treating the dispersoid with acid, washing, and dispersing again in pure water. The colloidal solutions may be used for disinfection, or for treating plants. Colloidal graphite is made by dispersing crude graphite with hot water, then cooling while under treatment, allowing to stand, decanting from the sediment, and drying.

Potash olein soap, barium, phenol-sulphonic acids such as naphtho-disulphonic acids may be added to accelerate the process of dispersion. Colloidal ultramarine is made by dispersing a mixture of coarse grained ultramarine and olein soap with water or an organic dispersion medium such as benzol, or alcohol with or without the addition of oil or turpentine: the product is dried. Other colors—e.g., iron, cobalt, zinc, lead, nickel or chrome colors—or lithopone or dyes may be similarly treated. Alkali, oils, or phenol-sulphonic acids may be used, instead of soap, as accelerators. An "enamel substance," such as artificial or natural resin, size, cellulose ester, copal, etc., may be dispersed in organic solvents for the production of enamels "in which the lakes are not dissolved but dispersed." Cellulose—for instance, wood pulp—is dispersed in water with or without the addition of gelatin, protein or soap and alkali, the cellulose is rendered flocculent by addition of acid, separated and dried under vacuum. The mass is homogeneous and may be pressed in molds. Organosols of cellular materials such as cellulose may be obtained by means of benzol, acetone, etc.; small quantities of cellulose ester soluble in acetone can be used as accelerators of dispersion. (Br. Pat. 155,836; not yet accepted; H. PLAUSON, Hamburg, and J. A. VIELLE, Westminster. See also Pat. 156,142. March 2, 1921.)

Arsenobenzene Derivatives.—Stable solutions are obtained by mixing solutions of 3:3'-diamino-4:4'-dioxyarsenobenzene sulphonylate and the sodium salt of 3:3'-diamino-4:4'-dioxyarsenobenzene or the complex silver compound thereof, or by mixing the two ingredients in powder form and dissolving the mixture. The resulting solution contains the two ingredients in chemical combination, that made from the sodium salt not being precipitated by carbon dioxide, and that made from the silver compound not being precipitated by salt or carbon dioxide. (Br. Pat. 155,577, not yet accepted; G. SPEYER HAUS, assignor to Farbwerke vorm. Meister Lucius & Bruning, Hoechst-on-Main, Germany; Feb. 23, 1921.)

Separation of Atmospheric Nitrogen.—Relates to the production of nitrogen by absorption of oxygen from a mixture of nitrogen and oxygen by means of metals such as iron, followed by the regeneration of the oxide produced; and consists in utilizing the heat generated by the absorption reaction to provide the heat required for the regeneration process. Since too large an excess of heat is developed by the use of atmospheric air in the absorption reaction, gases containing only about 10 per cent of oxygen are employed—e.g., flue gases from industrial plants, or mixtures of these gases with atmospheric air. The metal is contained in two shafts A, which function alternately as absorber and regenerator. Each shaft is connected at the top with a counter-current preheater E, by means of which the gases entering the shaft—namely, the mixture of nitrogen and oxygen supplied through pipe G or the reducing gas supplied through pipe I—are heated at the expense of the gases leaving the shaft; viz., pure nitrogen by the pipe L or exhauster reducing gas by the pipe N. The preheater can be short-circuited to any required extent by the valved pipe R. The shafts A are covered with adjustable heat-insulating plates D, in order to control the radiation of heat therefrom. The active mass of metal may also be varied. The danger arising from the formation of soot is avoided by introducing carbon dioxide into the water gas before it enters the regeneration apparatus. The carbon dioxide may be that contained in water gas which has already been through the apparatus. (Br. Pats. 155,814 and 155,815; not yet accepted; C. T. THORSELL and H. L. R. LUNDEN, Gothenburg, Sweden. March 2, 1921.)

Current Events

in the Chemical and Metallurgical Industries

Nitrogen Research to Continue

The U. S. Fixed Nitrogen Research Laboratory at American University, Washington, D. C., will be continued under War Department auspices for the present for the purpose of completing and rounding out experiments now under way and so that a comprehensive report of research activities on nitrogen fixation and utilization may be prepared. There is also a desire to continue this laboratory until the War Department is assured that it can obtain sufficient nitrogen from domestic sources to meet its needs. After that the laboratory is to be turned over to the Department of Agriculture, which is expected to continue the experimentation as to nitrogen fixation and utilization. No forecast can be given at this time as to when the transfer will be made.

This is a part of the ruling of the Secretary of War in the matter of the department's nitrate policy. He also decided that the Nitrate Division of the Bureau of Ordnance should remain as an entity. In addition he reached the conclusion that pending the development of the fixation of atmospheric nitrogen by private industry, to the point where an adequate supply of nitrogen to meet the government's requirements is assured, the government plants at Sheffield, Ala., and at Muscle Shoals, known as Plants No. 1 and No. 2, will be retained in the most economical stand-by condition.

The research work being done at the Fixed Nitrogen Laboratory is on a large scale. Expenditures in connection with that activity now are being made at the rate of \$250,000 a year. More than 100 chemists are employed. Work now will be concentrated on completing the present studies and designs of synthetic ammonia process and on the completion of a comprehensive report on nitrogen fixation and utilization.

Dye Control Amendment Goes to Senate

The emergency tariff bill was reported to the Senate April 30 containing Title V, which is to be known as the "dye and chemical control act, 1921." It was found that sufficient funds are now available to continue the work of dye and chemical control for another six months. This resulted in the elimination of the appropriation carried in the Knox amendment as originally drafted. Several other minor changes were made. As reported to the Senate the dye and chemical title reads:

Sec. 501. (a) That on and after the day following the enactment of this act, for the period of six months, no sodium nitrite, no dyes or dyestuffs, including crudes and intermediates, no product or products derived directly or indirectly from coal tar (including crudes, intermediates, finished or partly finished products, and mixtures and compounds of such coal-tar products), and no synthetic organic drugs or synthetic organic chemicals, shall be admitted to entry or delivered from customs custody in the United States or in any of its possessions unless the Secretary determines that such article or a satisfactory substitute therefor is not obtainable in the United States or in any of its possessions in sufficient quantities and on reasonable terms as to quality, price and delivery, and that such article in the quantity to be admitted is required for consumption by an actual consumer in the United States or in any of its possessions within six months after receipt of the merchandise.

(b) Upon the day following the enactment of this act the War Trade Board Section of the Department of State shall cease to exist; all clerks and employees of such War Trade Board Section shall be transferred to and become clerks and employees of the Treasury Department and all books, documents, and other records relating to such dye and chemical import con-

trol of such War Trade Board Section, shall become books, documents and records of the Treasury Department. All individual licenses issued by such War Trade Board Section prior to the enactment of this act shall remain in effect during the period of their validity, and the importations under such licenses shall be permitted. All unexpended funds and appropriations for the use and maintenance of such War Trade Board Section shall become funds and appropriations available to be expended by the Secretary in the exercise of the power and authority conferred upon him by this section.

Sec. 502. That this title may be cited as the "Dye and Chemical Control Act, 1921."

In its report urging the adoption of the title the Committee on Finance said:

At the present time the importation of coal-tar dyes and certain chemicals is regulated by means of licenses issued by the War Trade Board Section of the State Department, under the provisions of the trading with the enemy act approved Oct. 6, 1917, and the proclamation of the President of Feb. 14, 1918. It is deemed advisable to continue the present licensing system for a period of six months after the enactment of the proposed amendment in order that the Congress may have ample time to enact into law permanent tariff legislation covering importations of dyes and chemicals. The proposed amendment is deemed to be necessary because the powers of the War Trade Board Section of the State Department to grant licenses for the importation of dyes and chemicals are limited to the duration of the present war. The proposed amendment is limited to the dyes and chemicals the importation of which is now limited by licensing, and provides for the granting of licenses upon substantially the same terms as under the requirements for the importation of dyes and chemicals from enemy countries.

The proposed amendment provides for the transfer of the functions of the War Trade Board Section, including its clerks and employees, books, documents, and records, to the Treasury Department. The proposed amendment also provides that any unexpended funds and appropriations made for the use and maintenance of the War Trade Board Section shall be available to be expended by the Secretary of the Treasury in the exercise of the power and authority conferred upon him by the proposed amendment.

Annual Tables of Constants and Numerical Data

The publication of the Annual Tables of Constants and Numerical Data, Chemical, Physical and Technological, which was interrupted during the war, has now been resumed by an international commission acting under the authority of the International Union of Pure and Applied Chemistry.

Subscriptions to Volume IV, containing all numerical data published during the years 1913 to 1916 inclusive, will be received up to May 31 at the following rates: Part I only, \$12.50 bound, \$11 unbound; Parts I and II, \$25 bound, \$22 unbound. Part I, containing the constants from "Compressibility" to "Electricity," will be delivered probably early in July; Part II, with the remaining constants, some months later. Subscription blanks can be obtained from the American Commissioner, Prof. E. W. Washburn, University of Illinois, Urbana, Ill. Remittances should be made to the Chicago University Press, Chicago, Ill.

Orders for Volumes I, II and III will be received at \$7.20 each. Vol. I is, however, not sold separately, owing to limited supply. Volume V, covering the years 1917 to 1920 inclusive, is in preparation and will be ready for distribution late in 1922.

Preliminary Program, American Leather Chemists Association

At the meeting of the American Leather Chemists Association to be held at Atlantic City June 9 to 11 topics will be discussed which will be of interest to the practical men of the industry as well as the chemists.

The committee in charges announces the following preliminary program:

Colloids, Prof. Holmes (University of Cincinnati); Chestnut Wood Tannin, R. W. Griffith; Notes on the Extraction of Leather, Bureau of Chemistry; Post-Mortem Tests on Hide, G. D. McLaughlin; Moisture in Leather and Tannin Materials, T. D. Jarrell; Relation of South America to the Leather Industry, G. A. Kerr; Conditions in the Leather Industry, L. J. Robertson; Tanning Materials in the Far East, Dr. L. Balderston; Demonstration of the Explosiveness of Tannery and Leather Dusts, Bureau of Chemistry; Some Further Comments on the Wilson-Kern Method of Analysis, G. W. Schultz.

A symposium is to be held on the general subject of Synthetic Tannins. Various committee reports for the years 1920-1921 will be presented by the chairmen. The final program will be given out later.

Aims and Organization of the Materials Handling Division, A.S.M.E.

The new Materials Handling Division of the American Society of Mechanical Engineers is planning sessions for the discussion of "Design and Construction of Machinery for Road Building" at the Society's spring meeting to be held at the Congress Hotel, Chicago, May 23 to 26. Four papers will treat this problem from the viewpoint of the contractor, the road builder, and possible future development of mechanical equipment in road building.

The work of this Division, whose membership is rapidly approaching one thousand, is now well under way. The executive committee of the Division has adopted the report of the aims and organization committee, which mapped out a comprehensive working scheme. The executive committee is composed of R. M. Gates, chairman, Philadelphia; H. V. Coes, vice-chairman, New York; N. C. Johnson, New York; F. A. Wardenberg, Wilmington, Del.; and Kern Dodge, Philadelphia. The aims and organization committee is headed by F. M. Feiker of New York. Describing the aims of the Division, this report says:

"Materials handling is largely a mechanical engineering problem. It divides itself into two parts: (1) The consideration of the detailed design and operation of mechanical equipment for handling material, and (2) the economical and efficient application of this equipment in the arts and industries. The purpose of this Division is to organize, direct and promote these two foregoing objects. The formation of a Division will stimulate engineering thought and provide a method of expression which will make possible the more efficient methods and means of handling the commodities in our daily life. The Division shall have the following specific objects:

"To co-ordinate and correlate existing data and information, to find the gaps in the knowledge so as to bridge them, and to render the sum total available to the greatest possible number.

"To work toward standardization of methods and designs wherever feasible and possible with the belief that such standardization will reduce costs of handling materials.

"To promote actively the discussion of materials handling in all its economic and engineering phases to the end that it may take its rightful place in future engineering thought and opinion.

"To point out the economic wastes of duplication of effort, of manual labor and of undirected and unplanned material handling in all its phases.

"To aim to correlate the work of all engineers in materials handling.

"To co-operate with other divisions or other associations and organizations.

"To initiate and aid research.

"To assist in solving national, state and community handling problems.

"To establish an information division which would be prepared to furnish such information as a compendium of all devices now on the market, a list of references classified under materials handling."

The activities of the Division are outlined as follows:

"Materials handling in this division is concerned only with what may be called the problems of secondary transportation of materials and commodities. It does not concern itself with the broad transportation problems of the common carriers, or the tributaries to common carriers.

"Materials handling has to do with the multitudinous operations of 'picking up and putting down' materials in process of production, and the handling problems of the linkages between common carriers and delivery to the user."

Discussing the method of approach to the problem of materials handling, the report says:

"The objective in any materials handling problem is the reduction of costs. The professional division therefore will approach the problem in general as follows:

"Make a survey of the existing industry to ascertain the present state of the art.

"Make studies for the improvement of machinery and equipment for the handling of materials.

"Ascertain ways and means of reducing costs."

Prime consideration will be given to two sets of problems in the field of the Materials Handling Division: (1) The technical problems of the industries, and (2) the commercial fields of materials-handling machinery.

The report sums up the spirit of the new Division with this striking statement:

"The subject of materials handling should be taken out of a rule-of-thumb basis and put on an engineering basis in all its phases. To this end the Professional Materials Handling Division of the A.S.M.E. should devote itself."

Research Fellowships in the College of Mines, University of Washington

The College of Mines of the University of Washington offers four fellowships in mining, ceramic and metallurgical research in co-operative work with the Bureau of Mines. The fellowships are open to graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is \$900 per year of twelve months, beginning July 1. Fellowship holders are required to register as graduate students and to become candidates for the degree of Master of Science in mining engineering or metallurgy, or ceramics, unless an equivalent degree has previously been earned.

The purpose of these fellowships is to undertake the solution of various problems being studied by the United States Bureau of Mines that are of especial importance to the State of Washington, the Pacific Northwest and Alaska. The investigations consist principally of laboratory work directed largely by the bureau's technologists. For the year 1921-22 the following subjects have been selected for investigation:

(1) Beneficiation of coal, especially coal washing.

(2) Electrometallurgy. Electrothermic and electrolytic treatment of various mineral resources.

(3) Ceramics. Survey and testing of the clay resources of the Northwest to determine their economic utilization.

Applicants should send a copy of their collegiate records from the registrar's office of the college where they have been, or will be, graduated. They should also state their professional experience and give the names and addresses of at least three persons who are familiar with the character, training and ability of the applicant. Applications are due not later than June 1, and should be addressed to the Dean, College of Mines, Seattle, Wash.

Sugar Mills in the Hawaiian Islands Listed

Information concerning the sugar mills of the Hawaiian Islands, including the names of the companies, agents, location of factories, date of erection, and capacities, is contained in a list compiled by the Far Eastern Division, Bureau of Foreign and Domestic Commerce, Washington, for which request file No. FE-26004.

An Association of Employees' Clubs

On May 25 a conference will be held in New York City to effect organization of an association of the employees' clubs of America. Active membership will consist of clubs, associations or societies of employees of industrial, financial, mercantile or other organizations having for their main purposes social, athletic, educational, thrift and savings, health, safety or other similar mutual benefit activities; companies having "clubs" holding active membership will be associate members.

The direct purpose is exchange of such service, information and experiences between member clubs as will aid in increasing their usefulness and the enthusiasm of their membership. The more general purposes will be to promote better understanding and more cordial relations among employees and between employees and employers generally.

Plans for the organization have been under way for several months by a temporary committee with headquarters on the 22d floor, Times Building, New York City. All concerns or persons interested in such activities are urged to get in touch immediately with the chairman or other members of the executive committee: C. Lester Horn, chairman, 22d Floor, Times Building; Roger Steffan, educational director, National City Bank, New York City; L. W. DeMotte, director of personnel, American Express Co., 65 Broadway, New York City; D. A. Henderson, personnel manager, Knox Hat Co., 601 Grand Ave., Brooklyn, New York; J. Marshall, staff secretary, Alexander Hamilton Institute, 13 Astor Pl., New York City; George E. Morgan, welfare supervisor, Otis Elevator Co., 260 Eleventh Ave., New York City; Dr. C. E. Ford, General Chemical Co., 25 Broad St., New York City; MacLean Libbey, secretary, Stanley Insulating Co., 200 Fifth Ave., New York City.

Rochester Meeting, Division of Chemistry and Chemical Technology, Research Council

A meeting of the Division of Chemistry and Chemical Technology, National Research Council, was held at the Hotel Powers, Rochester, on the afternoon of April 27. Chairman Cottrell announced that the International Research Council would meet at Brussels on June 27 and that the United States is to be represented by six members. Prof. H. N. Holmes of Oberlin College presented a report reflecting favorably upon the activities of his colloid chemistry committee: Over 100 lectures had been delivered by members of the committee during the course of last year on various phases of colloid chemistry; the interest in colloid chemistry was increasing remarkably fast; Bancroft issued a long list of colloid chemistry problems, many of which have been taken up by the laboratories; Holmes issued a reference list of books and periodical literature compiled for those who cared to study the subject of colloids more fully; Bancroft and Holmes each published a book on colloid chemistry. An equally favorable and highly encouraging report was presented by Dr. E. W. Washburn on ceramic research during 1920. Among other things, a fellowship in ceramics has been established. In the discussion of the report it was suggested to include electrical porcelain in the program for this year. Dr. Bancroft reported on the activities of the contact catalysis committee, referring in particular to the very successful symposium recently held on the subject.

Charles E. Munroe, chairman of the committee on explosives investigations, outlined the work that his committee had performed during the past year: The list of literature references on explosives has been brought up to date, starting with the earliest publications; a detailed record of accidents has been kept, together with accounts of causes and suggestions for future prevention of such accidents. Dr. Munroe further suggested that the numerous investigations on explosives carried out during the war be written up, collected and published. Steps in this direction had already been taken by the British Government and a number of volumes already published.¹ The Council decided to take up Dr. Munroe's suggestion. Dr. J. M. Francis presented a brief report on pharmaceutical research; Dr. Stieglitz dis-

cussed the situation of research in synthetic drugs. Since the armistice the interest in research in these drugs has waned.

Dr. H. T. Clarke brought up the question of preparing lists of research chemicals. The difficulties encountered by investigators at present was to locate certain chemicals essential to their experiments. The idea was to prepare lists of both organic and inorganic chemicals with brief references as to where each could be obtained. The chair appointed a committee to undertake the work. A lengthy discussion followed on the publication of Tables of Critical Constants; Dr. H. K. Moore, chairman of the committee, reported that \$100,000 had been received in subscriptions. Dr. Johnson of Yale advised that Dr. C. J. West, formerly with A. D. Little, Inc., had been appointed editor of the tables.

At the conclusion of the meeting the following officers of the Division were elected for the ensuing year: Chairman, F. G. Cottrell; vice-chairman, Julius Stieglitz; executive committee, F. G. Cottrell, Julius Stieglitz, W. D. Bancroft, Colin G. Fink, W. F. Hillebrand, R. B. Moore; members at large, Treat B. Johnson, R. B. Moore.

Opposes Duty on Iron Pyrites

That a duty on pyrites will not protect the domestic product from sulphur competition was one of the arguments used by C. H. MacDowell, president of the National Fertilizer Association, who was granted a special hearing by the subcommittee on chemicals of the Ways and Means Committee of the House of Representatives. Mr. MacDowell stated that the production of pyrites from domestic sources is very expensive, in addition to being unsatisfactory in some ways for consumption by the interests which are large users of Spanish pyrites. A duty on pyrites, he declared, would have the effect of applying protection to sulphur, a product which exists domestically in such large quantities as to enable the United States to dominate the world's market and consequently is in no need of protection.

The chances seem favorable for some duty on potash. It is regarded as practically certain, however, that the committee will not approve as much as 50c. a unit, which was the amount asked by the domestic producers.

Every precaution is being taken by the members of the Committee on Ways and Means to prevent the dissemination of any information as to the schedules on which the subcommittees are agreeing. Due to the fact that these schedules are likely to be changed by the full committee it is believed that unnecessary agitation would be created by allowing the day-to-day conclusions to be announced. It is pointed out that ample time will remain after the permanent tariff bill is reported for those concerned to "shoot" at any of its schedules. The probabilities are that the bill will not be reported until near the end of May.

National Fertilizer Association to Meet at White Sulphur Springs

The twenty-eighth annual convention of the National Fertilizer Association, which will be held at White Sulphur Springs, W. Va., the week beginning June 20, 1921, will have a program of reconstruction and co-operation.

The program will include addresses and discussions on subjects that are of vital interest to the fertilizer manufacturer in view of present business conditions. These subjects will include costs and cost-accounting systems, chemical and manufacturing problems, sales methods, labor and transportation problems, etc. The officers of the association are now arranging the details and promise a meeting which will be of unusual interest and lasting benefit to everyone identified with the fertilizer industry. On account of the importance of the program a large attendance is expected.

During the same week the Southern Fertilizer Association will hold its summer meeting; the soil improvement committee of the National Fertilizer Association will hold a subscribers' and committee meeting; the soil improvement committee of the Southern Fertilizer Association will hold a committee meeting.

¹Publishers, His Majesty's Stationery Office, London.

Oilfield Developments in Northern Canada

The Canadian Department of Mines has changed its plans with regard to the method of transporting the geologists assigned to the Fort Norman and Windy Point districts. Arrangements had been made with the Canadian Air Force for the aerial transportation of both men and supplies, but this has been found to be too costly, and the slower, but possibly surer, method of transportation by barges is to be used. Barges are being constructed for the purpose, and will travel by way of the Peace, Slave, and Mackenzie rivers. The Imperial Oil Co. will adhere to its original plan of transporting men and supplies by air, the two all-metal airplanes already having made one trip to Windy Point, Great Slave Lake, carrying 1,000 lb. gasoline each. They returned without mishap, and, it is expected, will leave for Fort Norman within a few days.

A good deal of opposition is being brought against the bill in the legislature at Edmonton, Alta., to grant a pipeline right-of-way to the Imperial Oil Co. The route is not specified and very wide powers are asked. The company consequently has withdrawn the bill. The legislature will take up pipe-line legislation next session.

The Imperial Oil Co. will erect a small refinery near Fort Norman during the coming summer to provide gasoline for the company's airplanes and power boats. It is expected that a sufficient quantity will be made to supply other concerns in the district.

The British Columbia Department of Mines has let a contract to Lynch Bros. of Seattle to sink a 2,000-ft. bore-hole near the south fork of the Red River, about 20 miles northwest of Hudson Hope. Prof. John A. Dresser was employed to make a reconnaissance survey of the oil possibilities of this section of the Peace River region, and it is on his recommendation that the hole is being sunk.

Joint Brands and Trade Marks Used in Foreign Markets by U. S. Export Associations

A new feature in the development of foreign trade, reported by the Federal Trade Commission, is the adoption of joint, uniform brands and trade marks by associations organized under the Webb-Pomerene law for the purpose of export trade. Heretofore, in most cases, individual members of an association have retained their own marks on exports; but under the new plan an association brand or trade mark may be adopted to cover all goods shipped by the combine.

In advertising American goods abroad concentration on one or a few brands or marks which convey a guarantee of quality has proved to be much better business than the use by one association of a bewildering number of individual marks which may compete with one another and confuse the foreign buyer. Aside from advertising value, this feature represents an important step toward co-operation in export trade.

The U. S. Alkali Export Association of New York has abandoned the use of individual marks, and reports the adoption of a new association trade mark which will be advertised through agencies in South America, Cuba and Mexico.

The trade mark "Apex" is found on about 200 varieties of paper and board shipped by the American Paper Exports, Inc., of New York to Europe, Asia, Africa and South America.

The Consolidated Steel Corporation of New York advertises under the mark "Consteco."

Trade marks and stenciled designs are used by the Cement Export Co., Inc., of New York; the American Tanning Materials Co. of New York; and other associations operating in export trade under the Webb-Pomerene law.

Employment in Chemical Industries Decreases

A decrease of 2.3 per cent in employment in the chemical industries took place during April, according to an announcement by the Department of Labor. There was a decrease of 3.2 per cent in employment in the stone, clay and glass industries.

Administration Favors Fact Finding

Some opposition is being voiced in the non-metallic mineral industries to certain of the fact-finding activities of the Federal government. In that connection it may be mentioned that there is overwhelming opinion in Congress in favor of compulsory returns from industry of certain fundamental facts. It is the policy of the administration to favor legislation of this type, rather than that which contemplates regulatory supervision. For the immediate present it is expected that compulsory fact finding will be required only as to coal and three or four other basic industries. Once the legislative precedent is established, however, an extension of the policy could be put through promptly if it could be shown that the public interest would be served. One of the best ways to insure the enactment of such legislation is for producers to refuse to supply fundamental data voluntarily.

Aluminum Sulphate Used at Water-Purification Plants in Illinois, 1920

Data collected relative to use of aluminum sulphate at twenty-two of the water-purification plants in Illinois during 1920 show that 2,300 tons of alum was used, ranging from 5 tons at some of the smaller plants to about 780 tons at the largest plant. The cost ranged from \$24 to \$160 a ton. Analyses made at some of the plants show Al_2O_3 , 17 to 17.25 per cent; insoluble matter, 0.1 to 0.2 per cent; Fe, 0.5 to 0.75 per cent. In some instances the alum is purchased without specifications, and in others the specifications vary considerably. The alum has been purchased from four different companies.

Two Cent Duty on Sugar Asked

A duty of 2c. on imports of sugar is being urged by domestic cane producers for the permanent tariff bill. The emergency tariff measure carries a duty of 1.16c. per lb. It is understood that the subcommittee has decided on 1.6c. per lb. for the permanent tariff bill.

A duty of 100 per cent ad valorem is being urged for adonite, arabinose, dulcitol, galactose, inositol, inulin, levulose, mannitol, d-talose, d-tagatose, ribose, melibiose, dextrose testing above 99.7 per cent, mannose, melittose, raffinose, rhamnose, salicin, sorbitol, xylose and others of the higher saccharides required for scientific purposes.

Weights and Measures Conference

The fourteenth annual meeting of the National Conference on Weights and Measures will be held at the Bureau of Standards in Washington, D. C., May 23 to 26. The announcement by Representative Vestal that he sees no reason for delaying further the discussion before his Committee on Weights and Measures of the respective merits of the existing system of weights and measures and those of the metric system insures the discussion of that topic at the forthcoming meeting.

Congress May Ban Deceptive Containers

Legislation prohibiting the use of containers shaped so as to deceive or mislead the purchaser as to the "quantity, quality, size, kind or origin" of the contents may be expected at this session of Congress. It will be in the form of an amendment to the food and drugs act which has been introduced by Representative Haugen, chairman of the Committee on Agriculture.

To Investigate Muscle Shoals Projects

The American Farm Bureau Federation has appointed a committee to investigate thoroughly the questions involved in the Muscle Shoals controversy. The committee is authorized to engage engineers and to incur necessary expense of a thorough probe, with the idea of developing whether or not the government development on the Tennessee River would be beneficial to the agricultural industry. The committee consists of John Brown, Indiana; W. G. Jamison, Colorado, and Chester H. Gray, Missouri.

Personal

Dr. RAYMOND F. BACON addressed the Delaware Section of the American Chemical Society on Monday evening, May 2. His subject was "Some Problems in the American Sulphur Industry."

ERNEST J. P. BENN, member of Benn Bros., Ltd., publishers of the *Chemical Age*, London, England, and other technical magazines, who is making a visit to the United States, was entertained at luncheon at the Engineers' Club on May 5 by the Associated Business Papers, Inc.

EDMUND W. CRAFT of the Thermoid Rubber Co., Trenton, N. J., gave an interesting address on the subject of crude rubber before the members of the local Engineers' Club at a recent meeting. A. H. Greywacz, of the same company, followed Mr. Craft with a comprehensive talk on some of the technical features of rubber processes.

Dr. MAX MUELLER, president of the Rhodia Chemical Co., New York, is on a pleasure trip to the Pacific Coast, accompanied by Mrs. Mueller.

HOWARD M. RAYMOND has been appointed acting president of the Armour Institute of Technology to fill temporarily the vacancy caused by the death of Dr. F. W. Gunsaulus. Acting President Raymond is a graduate of the University of Michigan, and is well known professionally throughout the Middle West. He has been connected with the Institute for the past twenty-six years, and has served as dean of engineering since 1903.

Dr. JOHN E. TEEPLE has been elected president of the Chemists' Club.

JOHN THOMAS, the chief chemist of Scotch Dyes, Ltd., and J. E. Breckinridge, a director of the same company, both of Carlisle, Scotland, are in the United States on a business visit.

Obituary

ARTHUR R. WILLIS, chemical expert for the Tariff Commission, lost his life in an accident on the Potomac River Sunday, April 24. He was twenty-nine years of age and had been with the Tariff Commission nearly three years, having had charge of the compilation of the Census of Dyes and Coal-Tar Chemicals.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, May 9, 1921.

There was some improvement shown in chemical inquiries during the past week and reports of better business are becoming more frequent. Throughout the trade the month of April seems to have shown a decided change over previous months. The inertia of the market has necessarily made the change gradual, nevertheless activity is moderately increasing. While at the present rate it will still require a number of months to reach anything like normal conditions, the progress is encouraging. The labor and freight problems are still the most unfavorable factors confronting the producers of chemicals.

FOREIGN COMPETITION

Foreign competition is being strongly reflected in the chemical market. Imported materials are still figuring

very largely in the situation and in the majority of cases domestic manufacturers realize the futility of trying to meet the importers' prices. There are a few cases, however, where competition is keen between domestic and foreign goods for interior points, with the advantage resting with the manufacturer on account of freight charges. Imported *prussiate of soda*, *citric* and *tartaric acids*, *chlorates*, *bleach* and *caustic potash* are being offered below producers' prices here. *Soda ash* is another item that is attracting some attention. This chemical has been sold for shipment in practically every case. It is understood that sellers of this material are not eager to bring ash in unless sold ahead. Prompt shipments of ash were offered by importers at \$1.90 per 100 lb. ex-dock New York. Producers have not announced any further change in either ash or caustic soda prices and it is understood that a fair business is being placed for home consumption in both items. Standard brands of caustic soda and soda ash have remained steady on spot and the market looked firmer at the close than it did at the opening. The call for small lots of bichromate of soda was sufficient to hold the market around 7½c. per lb. Imported prussiate of soda was slightly firmer during the week under tighter offerings and a better inquiry. Oxalic acid has maintained a firm tone on both foreign and domestic material and demand has kept prices at 17c. per lb. and above all week.

OUTLOOK MORE FAVORABLE

The outlook in general may be considered more favorable. A settlement of the German reparations question will bring about a far-reaching change in affairs. The position of the Allies would be materially strengthened financially and otherwise. It will mean an early revival of trade with Europe. International credits and exchanges would soon be stabilized. With the return of the second greatest trading nation a new revival in world commerce would be seen everywhere. Additional markets for American goods, therefore, would be opened.

GENERAL CHEMICALS

Hydrochloric acid prices are fairly steady in the absence of any pronounced activity. Commercial acid in carboys is quoted at prices based on \$1.65 per 100 lb. for the 20 deg. grade. Larger quantities could be obtained down to \$1.50. Following continued shading in various directions, makers are now quoting lower prices on 66 deg. sulphuric acid. Prices based on tank carlots f.o.b. works are quoted at \$18@20 per ton. Business has been rather slow. Prices on *oleum* and 60 deg. acid have remained practically unchanged. Lack of demand for *ammonium sulphate* prevents possible firmness and prices, while quoted on the former basis, are subject to shading in all directions. Quotations of \$2.75 per 100 lb. for export in double bags can undoubtedly be shaded to a decided extent and the bulk price at works, which has been quoted at \$2.75, can now be had as low as \$2.50 per 100 lb. White *arsenic* can be had as low as 7½c. per lb., although there are a few holders in the market at 8c. per lb. Little interest has been noted in the *bleach* market during the week and prices have been easy in most directions. The resale market is around \$2.50 per 100 lb., with works delivery from second hands down to \$2.25. Manufacturers are holding their quoted prices around \$2.75 per 100 lb. f.o.b. works. Resale *bichromate of potash* is not in heavy supply at present and most dealers quote 11¼@12c. per lb. for limited quantities. In some quarters sales of odd lots have been made down to 11½c. per lb.

Makers of *caustic potash* are quoting lower prices based on 12c. per lb. for the 88-92 per cent material and are unable to attract buyers in view of the state of the market. Resellers of American reshipped material are offering at 4½c. per lb., but the condition of these goods is very doubtful. Importers are quoting German potash at 5½@6c. per lb. An advance in shipment prices from abroad in *prussiate of soda* had a strengthening influence on spot quotations. At the close the market was quoted firm at 11¼@12½c. per lb. The market on *carbonate of potash* continues inactive and prices are rather soft. Offerings of 96-98 per cent

carbonate are heard at 9c. per lb. Holders of this and lower grades are eager to accept any reasonable offer on their material. Makers of *salt cake* are in a position to offer their goods below recent figures. Prices are now named at \$30@\$35 per ton for the bulk. Resellers and importers of *acetate of soda* are competing at prices around 4½c. per lb. Makers are holding off and their prices are around 6½c. per lb. Spot offerings of *nitrite of soda* are not to be found below 5½c. per lb. Stocks in resale hands are still heavy, although the market generally shows signs of strength. Improvement in demand for *copper sulphate* has taken place during the week and considerable business has been placed for agricultural requirements. Export inquiries have also increased and it looks as though France, Italy and South America are going to be fair buyers. In the case of European countries their production is restricted on account of the scarcity of raw material and they are looking to America for supplies. The domestic copper market has remained quite firm for the past few weeks and this condition seems to have convinced consumers of the sulphate that the market has really reached bottom. Leading producers quote carlots at 5½c. per lb. for the standard 99 per cent large crystals. The outlook for business in this chemical is considered better than for some time past. Moderate quantities of standard brand *caustic soda* were on the market around \$3.65@\$3.70 per 100 lb. ex-store N. Y. and \$3.75 f.a.s. steamer. Carlot trading has remained rather quiet in the open market, although it is understood that producers have been able to place a fair business at the works. Contracts are quoted at 3½@3¾c. per lb., basis 60 per cent f.o.b. works. Resale lots of light *soda ash* in single bags were distinctly firm in the final trading and dealers stated that it is doubtful if spot material could be purchased under \$2.05 per 100 lb. Barrels sold higher at \$2.30 per 100 lb. The feeling on spot goods was very steady even though a considerable amount of imported goods was noted to arrive. At the works producers quoted \$1.62½@\$1.72½ per 100 lb., basis 48 per cent, for single bags.

COAL-TAR PRODUCTS

A revival of interest in some directions has been noted in the coal-tar products market. Some very sizable orders have been placed in the resale market during the week, but as a rule sellers have been forced to sacrifice on prices. After the long period of inactivity, however, any movement is a welcome sign to holders. Those with any accumulated stocks are so tired that they are willing to make any concessions that will start some active trading. It is only recently that consumers have been willing to exhibit any interest in taking on stocks. Few price changes have been noticed which can be taken as indicating anything radical. The crude market remained steady during the week with a fair trading in *benzene* and *naphthalene*. Intermediates in general are in better demand with no special changes.

There were rumors of new strength in *benzene* without any confirmation. Competition among refiners has been quite keen for any business that has been around and offers have been made at prices below quotations where there was a possibility of developing actual business. Quotations on pure benzene are based on 27c. per gal. in tank cars and range up to 32c. in drums. *Aniline oil* ranges from 21@26c. per lb. *Beta naphthol* sales in some large volume have been reported in the resale market during the week. The prices quoted have undergone no noticeable change as the transactions were more or less of a private nature. Offerings were generally around 33c. per lb. with sales recorded down to 32c. Makers are finding no business at their quoted prices of 40@45c. per lb. Factors of *H acid* say that the past week has witnessed a little better movement and views of prices of first hands are steady at \$1.40 per lb., while in resale quarters the market was easier and shading possible at \$1.20@\$1.25 per lb. There was little change noted in the market on *benzidine* and trading was moderate with supplies rather steady. The base material ranges from 90@95c. per lb. and the sulphate from 80@85c. Inquiries for *phenol* were more frequent and actual trading was reported in some quarters on a larger scale. Government supplies are still available at 12c. per lb., while in

other quarters nothing much under 10c. was thought possible.

WAXES

Prices on *beeswax* were unsettled, due to freer offerings and rather moderate buying interest. Pure white wax was offered at 45@47c. per lb. with the undertone easier. Crude Brazilian was nominally held at 21@23c. per lb. For the African grade of crude the market closed around 15½@16½c. per lb. Recent heavy importations of *carnauba wax* resulted in easing the spot situation and at the close offerings of the higher grades were noted at 60@62c. per lb. No. 2 North Country was available at 28@30c. per lb., while these figures could have been shaded on actual business. Spot offerings of *Japan wax* were reported at 18@18½c. per lb., indicating that prices were a shade easier. Demand for spot material was quiet and with futures unsettled interest in forward business was also lacking. Despite the uplift in crude petroleum the market for *paraffine wax* was easier throughout the week. Refiners appeared more anxious for business and offerings for scale wax were noted here at prices ranging from 2½@2¾c. for carlots, immediate shipment. Refined paraffine also came out in large volume and at the close there were sellers of 125-127 deg. melting point at 4½c. per lb., with the 130-132 deg. m.p. at 5@5½c. The presence of some distressed material had a depressing influence on the market.

The Chicago Market

CHICAGO, May 6, 1921.

An improvement in the general tone of the industrial chemical market was evident during the past week. Naturally this was noticeable only in certain sections of the market, but the fact that there is any business at all is considered most encouraging. Price changes were few, and most factors seem to think that the majority of items have reached bottom. However, there are several items on the list that are far from the normal level and can be expected to go lower. One of the more important ones in this class is *potassium permanganate*, which has shown a steady decline during the past two months. This material is now offered at 38@40c. per lb. In contrast with the pre-war price of 8@10c., it is only reasonable to expect further reductions.

GENERAL CHEMICALS

Soda ash is quiet, the prevailing quotations being 2½@2¾c. per lb. in small quantities. Caustic soda, 76 per cent, is quite firm and is quoted at \$4.10 per 100 lb. for the solid and \$4.75 for the ground. Holders show no disposition to shade these figures and claim that they are doing a fair volume of business. White granular *ammonium chloride* is in better demand and 9c. per lb. for large casks was the best offer noted. Non-beverage *alcohol*, 190 proof, is quoted by distillers at \$4.85 per gal. for single drums. The completely denatured is lower and No. 6 is available from first hands at 33c. per gal. in 5-drum lots. The mild winter left large quantities of this material on the market and it is available from the holders at almost any price.

Barium chloride is unchanged and is quoted at \$75@\$80 per ton. *Carbon tetrachloride* is very firm and it is doubtful if supplies could be had at a figure lower than 11½c. per lb. *Carbon bisulphide* has also shown a firm tendency and spot material is quoted at 8@8½c., according to quantity. *Formaldehyde* showed a further decline and first hands are asking 15½c. per lb. for barrels. The demand has dropped off somewhat and there seems to be little moving at the present. *Potassium carbonate*, 80-85 per cent, is quoted nominally at 11c., but with large business concessions could probably be secured. Second hands still have control of the *caustic potash* market and 88-92 per cent material is available at 8@8½c. per lb. *Bichromate of potash* is steady, the prevailing quotation being 14½c. per lb. for single casks. *Sodium bichromate* is very firm and holders are asking 9@10c. per lb. for material of standard brands. *Glycerine c.p.* is firmer and is moving in a small way at 17c. per lb. for large or small drums.

The list of acids is unchanged and manufacturers do not seem to contemplate price reductions, at least not in the near

future. There is a fair quantity of *acetic acid*, 28 per cent, moving to the photographic trade at 2½@3c. per lb. in barrels. *Hydrochloric acid* is in limited request and is offered at 2@2½c. per lb. in carboys. There is a somewhat better demand for *sulphuric acid*, which is offered at \$19@ \$20 per ton in tank cars or 2@2½c. per lb. for carboys.

VEGETABLE OILS

Quiet conditions still prevail in this branch of the trade and dealers express little hope for better conditions for several months. *Palm oil* is quoted at 8@10c. per lb., according to the holder. *Soya bean oil* is extremely quiet and is offered at 7½@8c. per lb. in small lots. *Linseed oil* is higher, dealers asking 65@67c. per gal. for the boiled with corresponding prices for the raw.

NAVAL STORES

The local market for naval stores has shown a considerable improvement during the past two weeks. *Turpentine* was advanced sharply, most factors asking 74c. per gal. for a good grade material. *Rosin* is still available at \$8 per 280 lb. for the WG grade, but dealers say that higher prices can be expected.

COAL-TAR PRODUCTS

There were no noteworthy features in the coal-tar market and business was of the same quiet nature that has been characteristic of this branch of the trade for several months. Prices were unchanged, *benzene* being offered at 28@31c. per gal. for the 90 per cent and 30@33c. for the pure. *Toluene* is available at 33c. for the refined grade. *Naphthalene flakes* are moving in a small way to the wholesale drug trade and are offered at 8½@10c. per lb.

The St. Louis Market

ST. LOUIS, May 6, 1921.

Inaugurating our St. Louis letter, we wish to point out that the market comments will be confined chiefly to those articles which are produced and consumed in St. Louis or which move in volume through this distributing center.

Conditions during the past two weeks show some improvement and the general tone is optimistic.

ALKALIS

The *caustic soda* market is very unsettled due to the large consumers buying only for their immediate needs on the spot market and not anticipating their requirements or entering contracts. Prices are \$3.85@\$4.50 per 100 lb. There is little activity in *soda ash*, with a few carload sales reported recently. Round lots are quoted at \$2.95@\$3 per 100 lb., basis 58 per cent. *Sal soda* is moving in the routine way at \$1.95@\$2.50 per 100 lb. *Bicarbonate of soda* is very inactive.

INDUSTRIAL CHEMICALS

There has been no change in price of *aqua ammonia*, and a fair business is being done. The market for *carbon bisulphide* is very firm and buyers should have no hesitancy in ordering liberal quantities. *Copperas* is moving in a fair way and is quoted at 90c.@\$1.00 per 100 lb. f.o.b. producer's works. There has been a decline recently in *sulphur* of ½c. per lb., but this has been counterbalanced by an equal advance in freight rates in the past two weeks. Therefore, *sulphur* continues to hold at 2c. per lb. for the commercial flour.

DRUGS AND PHARMACEUTICALS

Apparently the *acetone* market is firm at 12½@13c., with occasional second-hand lots being offered at a lower figure. There has been a marked improvement in *bismuth* preparations in the past two weeks, the increased demand being probably due to the favorable prices at which they are quoted. The demand for *bromides* is fair, but buyers are ordering only for their immediate needs, hence the market is weak. *Cream of tartar* is in greater demand than expected but *acid tartaric* is weak. *Glycerine* continues weak at 16½c., with no great demand. *Salicylates* are moving fairly well, and there should be no question about buying, as prices have probably reached their lowest.

A fair volume of business in *sodium benzoate* is reported and should show a decided increase very shortly with the approach of the preserving season. Prices on *zinc oxides* remain the same, with an increasing demand for the lead-free, probably due to the revival of the rubber industry. A good volume of business in *zinc stearate* is being done and should continue in view of the summer demand.

VEGETABLE OILS

Linseed oil reacted the past week to a 66c. maximum and is today quoted at 64c. warehouse and in cooperage or 61c. carload for direct shipment from crushers. *Castor oil* is reacting from its low position and is now holding at 9½c.@10c. with a fair demand. *Turpentine* has slowly reacted and is now quoted at 63½c. The recent cold weather has had its effect on the crops to the extent that the yield will be decreased at least 75 per cent in this territory, and as a consequence there is no activity in *insecticides* except for *paris green*, for which there is a good demand on a 30c. basis.

PAINT MATERIALS

The *barytes* market is very firm, with prime quality holding at \$25.50@\$26.50 f.o.b. mills. Apparently the unsettled condition in *lithopone* is disappearing due to the carload buyers again purchasing their usual quantities, and continued activity is expected. Prices are 7@7½c. carload.

ACIDS

The demand for *acids* has been very good and in view of the import price now being on a higher basis than the domestic manufacturers' prices there should be a material increase in sales. *Phosphoric acid sirupy*, with the approach of the soft-drink season, should show quite a bit of life and move in larger volume in the next few weeks. Sales of *gallic*, *pyrogallie* and *tannic acid* have shown a decided increase lately, with many large orders originating in England.

The Iron and Steel Market

PITTSBURGH, May 6, 1921.

Conditions in the iron and steel trade this week are distinctly disappointing, not because they have grown worse, but because they do not record the improvement that was expected from the occurrences of three weeks ago. According to the expectations there should be more business on mill books and a larger operation, but there is not.

In the price equalization of three weeks ago, from a condition in which the independents had much lower prices than the Steel Corporation, the independents advanced their prices somewhat, while the Steel Corporation reduced its prices. As the independents were withdrawing their former prices, they allowed buyers to take advantage of the previous quotations on such tonnages as they were able to specify. By this operation it was thought the independents had rolled up a considerable tonnage of actual business, such as would give them a larger operation. By the Steel Corporation's reducing its prices and of course concurrently revising prices in contracts outstanding, it was the expectation that the corporation would receive specifications against its contracts at a much heavier rate.

The condition the past week, however, has been that the independents have been receiving very little new business and the Steel Corporation has been receiving specifications at what is, on the whole, a very low rate.

The average operating rate of the independents, developed from a symposium of estimates, appears to be only about 30 per cent of capacity, a rate no better than the poorest rate since Jan. 1 and probably somewhat under the maximum rate, which seems to have fallen about April 1. As to the Steel Corporation, its rate is generally believed to be several points below 40 per cent of capacity and at nearly if not quite the poorest rate of the year. In January the Steel Corporation operated at about 90 per cent and the independents at about 30 per cent.

Production of pig iron by the merchant furnaces is at a still lower rate, only between 15 and 20 per cent of capacity. That is to be explained chiefly by the fact that there are stocks of pig iron to be consumed. The great majority of

merchant furnaces are now out of blast, but roughly speaking before the furnaces went out they provided customers with all the pig iron they would take on contract, and also piled iron in their own yards. Doubtless the rate of consumption of merchant pig iron is low, but in all probability it is considerably greater than the present rate of production.

STEEL PRICES HOLDING

The new steel prices are holding, but the real test must come later. There is no incentive at present to cut prices, inquiry being so light. Quotations on leading products are: Billets, \$37; slabs, \$38; sheet bars and small billets, \$39; rods, \$48; bars, 2.10c.; shapes, 2.20c.; plates, 2.20c.; hoops and hot rolled strips, 2.75c.; plain wire, 3c.; wire nails, \$3.25; steel pipe, 61½ per cent basing discount; blue annealed sheets, 3.10c.; black sheets, 4c.; galvanized sheets, 5c.; tin plate, \$6.25.

WAGES

The United States Steel Corporation has announced a general wage reduction, effective Monday, May 16. Common labor is reduced approximately 20 per cent, which presumably means from 46c. to 37c. as the hourly rate, with an adjustment of other wage rates and of salaries. The independents began reducing wages early in December, there being no regularity or uniformity. Some made one large reduction, others two or three smaller ones at intervals. The last important reductions by independents were at the middle of February, involving the leading independents in the Mahoning and Shenango valleys and the leading independent in the Pittsburgh district. While the independent rates have not been uniform, they average about the same as the rates to which the Steel Corporation is now going, from three to five months after the independents took their various actions.

The Steel Corporation makes no change in working conditions, but states that the 12-hour day will probably be eliminated within a year. The basic 8-hour day remains quite generally in force where it previously obtained, men being paid time and a half for hours in excess of eight.

One is given to understand that the Steel Corporation's wage reduction is in relation to the price reductions the corporation made three weeks ago, so that no further modification of the corporation's prices is to be expected at this time. However, the announcement does not seem to have any stimulating influence upon steel buyers, it being regarded rather as a disturbing factor at the moment.

PROSPECTS

Obviously the consumption of steel is at a very low rate compared with the activity of the first nine months of last year, so that there is no prospect of steel being required from the mills at higher than the present rate as long as fundamental conditions remain as they are. The common view is that there will be no material change until next fall, and by reason of temperamental or other differences the time for a definite improvement is variously set from August to October.

PIG IRON

Basic iron remains quotable at \$22.50 valley, with only a very occasional transaction. Foundry iron is quotable at \$24, a 50c. decline, while bessemer remains nominally at \$25. Price prospects are complicated by the fact that freight rate reductions are expected at some indefinite time in the future. Possibly the development of anything like a widespread demand would produce competitive bidding for orders.

COKE

Connellsville coke does not continue to decline as was expected in some quarters. The furnace at Portsmouth, Ohio, which over a month ago bought coke at \$3.50 has renewed the contract for thirty or sixty days more, 500 tons a day, at the reported price of \$3.40, but only the producer holding this contract seems willing to go below \$3.50. Foundry coke remains quotable at \$5 to \$5.50. Prices are per net ton at ovens.

Beta-naphthol, sublimed.....	lb.	.70 - .75
Beta-naphthol, tech.....	lb.	.33 - .45
Beta-naphthylamine, sublimed.....	lb.	2.00 - 2.25
Cresol, U. S. P., in drums (100 lb.).....	lb.	.16 - .18
Ortho-cresol, in drums (100 lb.).....	lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums.....	gal.	.90 - .95
Cresylic acid, 75-97%, dark, in drums.....	gal.	.85 - .90
Cresylic acid, 50%, first quality, drums.....	gal.	.55 - .60
Dichlorobenzene.....	lb.	.07 - .08
Diethylaniline.....	lb.	1.20 - 1.25
Dimethylaniline.....	lb.	.45 - .55
Dinitrobenzene.....	lb.	.30 - .32
Dinitrochlorobenzene.....	lb.	.20 - .30
Dinitronaphthalene.....	lb.	.30 - .40
Dinitrophenol.....	lb.	.35 - .40
Dinitrotoluene.....	lb.	.25 - .27
Dip oil, 25%, tar acids, car lots, in drums.....	gal.	.40 - .45
Diphenylamine.....	lb.	.60 - .70
H-acid.....	lb.	1.30 - 1.50
Meta-phenylenediamine.....	lb.	1.20 - 1.25
Monochlorobenzene.....	lb.	.12 - .14
Monoethylaniline.....	lb.	1.75 - 1.85
Naphthalene crushed, in obls. (250 lb.).....	lb.	.08 - .08½
Naphthalene, flake.....	lb.	.08 - .09½
Naphthalene, balls.....	lb.	.09 - .10½
Naphthalenic acid, crude.....	lb.	.70 - .75
Nitrobenzene.....	lb.	.12 - .15
Nitro-naphthalene.....	lb.	.30 - .35
Nitro-toluene.....	lb.	.16 - .18
Ortho-amidophenol.....	lb.	3.15 - 3.40
Ortho-dichlor-benzene.....	lb.	.15 - .20
Ortho-nitro-phenol.....	lb.	.75 - .80
Ortho-nitro-toluene.....	lb.	.17 - .20
Ortho-toluidine.....	lb.	.20 - .25
Para-amidophenol, base.....	lb.	1.60 - 1.75
Para-amidophenol, HCl.....	lb.	1.75 - 1.85

Para-dichlorobenzene.....	lb.	.15 - .20
Paranitroaniline.....	lb.	.85 - 1.05
Para-nitrotoluene.....	lb.	.85 - 1.00
Para-phenylenediamine.....	lb.	1.95 - 2.00
Para-toluidine.....	lb.	1.25 - 1.60
Phthalic anhydride.....	lb.	.50 - .60
Phenol, U. S. P., drums (dest.), (240 lb.).....	lb.	.11 - .13
Pyridine.....	gal.	2.00 - 3.50
Resorcinol, technical.....	lb.	1.75 - 1.85
Resorcinol, pure.....	lb.	2.25 - 2.30
Salicylic acid, tech., in bbls. (110 lb.).....	lb.	.22 - .23
Salicylic acid, U. S. P.....	lb.	.21 - .22
Salol.....	lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal.....	gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal.....	gal.	.14 - .16
Sulphanilic acid, crude.....	lb.	.30 - .35
Tolidine.....	lb.	1.35 - 1.45
Toluidine, mixed.....	lb.	.40 - .45
Toluene, in tank cars.....	gal.	.25 - .28
Toluene, in drums.....	gal.	.28 - .31
Xylidines, drums, 100 gal.....	lb.	.40 - .45
Xylene, pure, in drums.....	gal.	.42 - .45
Xylene, pure, in tank cars.....	gal.	.45 - .45
Xylene, commercial, in drums, 100 gal.....	gal.	.33 - .35
Xylene, commercial, in tank cars.....	gal.	.30 - .35

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark.....	lb.	\$0.23 - \$0.25
Beeswax, refined, light.....	lb.	.25 - .27
Beeswax, white pure.....	lb.	.45 - .47
Carnauba, Flora.....	lb.	.60 - .61
Carnauba, No. 2, North Country.....	lb.	.28 - .30
Carnauba, No. 3, North Country.....	lb.	.17 - .18
Japan.....	lb.	.18 - .18½
Montan, crude.....	lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p.....	lb.	.04 - .04½
Paraffine waxes, crude, scale 124-126 m.p.....	lb.	.03 - .03½
Paraffine waxes, refined, 118-120 m.p.....	lb.	.03 - .04
Paraffine waxes, refined, 125 m.p.....	lb.	.04 - .04½
Paraffine waxes, refined, 128-130 m.p.....	lb.	.04 - .05
Paraffine waxes, refined, 133-135 m.p.....	lb.	.06 - .06½
Paraffine waxes, refined, 135-137 m.p.....	lb.	.06 - .06½
Stearic acid, single pressed.....	lb.	.09 - .10
Stearic acid, double pressed.....	lb.	.10 - .11
Stearic acid, triple pressed.....	lb.	.11 - .11½

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl.....	280 lb.	\$5.50 -
Rosin E-I.....	280 lb.	6.30 - 6.40
Rosin K-N.....	280 lb.	6.50 - 6.70
Rosin W. G.-W. W.....	280 lb.	6.80 -

Plates, 1/2 to 1 in. thick.....	2.50	3.30	3.23

*Add 10c per 100 lb. for trucking to Jersey City and 15c for delivery in New York and Brooklyn

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

Arkansas

FORT SMITH.—The Fording Refinery Co., recently organized with a capital of \$250,000, has acquired property at Van Buren, Ark., comprising about 17 acres of land, as a site for the erection of a new oil refinery with initial daily capacity of about 500 bbl. A plant for the extraction of gasoline will also be constructed. E. F. Blanchard is president, and John H. Vaughn, secretary.

Alabama

ANNISTON.—The Anniston Electric Steel Co., recently organized, is considering the erection of a number of additions to the plant of the Anniston Steel Works, which it has acquired for the manufacture of electric steel products. The company will make a specialty of electric steel castings, gray iron and other castings. G. C. Illingworth is vice-president and general manager.

BIRMINGHAM.—The Johnson-Thompson Foundry Co., North 26th St., is planning for the erection of an addition to cost about \$22,000.

California

LOS ANGELES.—The Co-Operative Glass Co., Bank of Italy Bldg., has filed plans for the erection of a new plant at 751 South Daly St., to comprise mold shop, 40 x 75 ft., and main glass manufacturing works, 90 x 180 ft. The Pozzo Construction Co., 421 Macy St., has the building contract.

DOWNEY.—The West Coast Asbestos Co. is planning for the erection of a number of new buildings at its local plant. Equipment will be installed to double the present capacity.

Delaware

WILMINGTON.—The Atlas Powder Co., du Pont Bldg., is planning for the erection of a new plant for the manufacture of carbon products, to be operated by its subsidiary organization, the Darco Corp. The new plant will have an initial output of 6,000 tons, and will include refining works and other departments.

Georgia

MACON.—The Buckeye Cotton Oil Co. is reported to be planning for the rebuilding of its local plant, recently destroyed by fire with loss estimated at about \$135,000, including machinery.

ATLANTA.—The Diamond Holdfast Rubber Co., 33 Auburn Ave., has acquired property totaling about 11 acres, as a site for the erection of a new plant for the manufacture of rubber products, including rubber cement and adhesive rubber compounds. The works will comprise a group of buildings, with main 2-story structure.

Indiana

DUNKIRK.—The Indiana Glass Co. has awarded a contract to the Austin Co., Euclid Ave., Cleveland, O., for the erection of a new 1-story manufacturing plant, 60 x 100 ft.

JEFFERSONVILLE.—Colgate & Co., 105 Hudson St., Jersey City, N. J., manufacturer of soaps and kindred products, has acquired the Indiana Reformatory property at Jeffersonville, from the state, for the establishment of a new branch plant. The company will take possession of the property within a few months and will remodel the different structures and install necessary machinery. The works will specialize in the manufacture of soap products, washing powders and cleansing compounds. It is expected to give employment to about 1,000 operatives for initial operatives.

Louisiana

SHREVEPORT.—The United States Window Glass Co., Morgantown, W. Va., is perfecting plans for the erection of its proposed new plant at Shreveport, to consist of a number of 1- and 2-story buildings, estimated to cost in excess of \$2,000,000 with

machinery. The company is operating a plant at Morgantown, and was recently incorporated with a capital of \$4,000,000. Walter A. Jones is president. The DeVore Co., 908 Nicholas Bldg., Toledo, O., is architect and engineer for the new Shreveport plant.

Maryland

BALTIMORE.—The United States Industrial Alcohol Co. is having plans prepared for the erection of a 1-story addition to its plant in the Curtis Bay section, 60 x 180 ft. The company has recently filed plans for another building at the plant to cost about \$18,000.

FROSTBURG.—Fire, April 22, caused by an explosion, destroyed a portion of the works of the Big Savage Fire Brick Co., with loss estimated at about \$25,000.

MOUNT SAVAGE.—The Mount Savage Fire Brick Co. has awarded a contract for the erection of an addition to its plant to Golin Gerlach, Frostburg, Md. A power plant will also be constructed.

Minnesota

MINNEAPOLIS.—The Minnesota Mfg. Co., 722 North 3d St., manufacturer of sweeping compounds and other chemical products, is having plans prepared for the erection of a 2-story and basement plant, 16 x 132 ft., on Eighth St., near Third St. Perry Crosier, 915 New York Life Bldg., is architect.

Missouri

ST. LOUIS.—The Herman Oak Leather Co., 4030 North Main St., is taking bids for the erection of a 2-story and basement plant addition, 25 x 70 ft., to cost about \$22,000. L. C. Herman is head.

KANSAS CITY.—The Standard Steel Works, 1722 Tracy St., will break ground at once for the erection of a new 2-story addition 25 x 115 ft., at North Kansas City, to cost in excess of \$55,000. Contract for erection recently was awarded to Fred Crites, 2136 Bellevue Ave.

New Jersey

CAMDEN.—The Camden Coke Co. is arranging for the installation of a new battery of coke ovens. The company is a subsidiary of the Public Service Corporation, Newark, N. J., which has secured permission from the Board of Public Utility Commissioners to issue notes for \$1,496,000 to defray the cost of the work.

NEWARK.—The Celluloid Co., 290 Ferry St., is having plans drawn for the erection of an addition to its plant. Alterations and improvements will also be made in existing buildings at the plant.

NEW BRUNSWICK.—Johnson & Johnson, manufacturers of chemicals, drugs, etc., will dispose of a portion of their local plant, consisting of a 2-, 3- and 5-story building, totaling about 122,215 sq.ft. in area.

NEWARK.—The American Pipe & Bending Co. has taken bids for the erection of a new 1-story plant on Coit Street, 60 x 120 ft., to cost about \$20,000. Strombach & Mertens, 1091 Clinton Ave., are architects.

New York

BROOKLYN.—The Burley Welding Works, 22-24 Kosciusko St., is taking bids for the erection of a new 3-story plant, 40 x 100 ft., to cost about \$50,000. Edward M. Adelson, 1778 Pitkin Ave., Brooklyn, is architect.

Oklahoma

SAND SPRINGS.—The Oklahoma Tanning & Mfg. Co., Tulsa, has acquired property at Sand Springs, totaling about 5 acres, for the erection of a new leather tannery. The initial works will cost about \$45,000. Uley Holderman is president.

Pennsylvania

ERIE.—The Keystone Rubber Co., 11th St., is reported to be planning for the rebuilding of its plant, destroyed by fire, April 28, with loss estimated at about \$500,000, including machinery. The fire was caused by an explosion of chemicals.

AMBRIDGE.—The Columbus Steel & Shafting Co., Carnegie, Pa., has completed plans for the erection of its proposed new plant at Ambridge, to consist of a group of 1-story buildings, estimated to cost about \$3,000,000 with machinery. Hopkinson & Schaeffer, 500 Marion Bldg., Cleveland, O., are architects.

Tennessee

CHATTANOOGA.—The Signal Mountain Cement Co., 1022 James Bldg., will soon take bids for the erection of a new local plant for the manufacture of cement, estimated to cost in excess of \$200,000. A. F. Miller, 205 James Bldg., is engineer.

Texas

BURNET.—The Sulphur Oil Co. is planning for the development of ichthyol properties in this section. The company has extensive deposits and it is said that so far as is known at the present time, the material is not found in any other place in this country. A retining plant is proposed for the production of ammonium ichthyolate from the raw material.

COMMERCE.—The Trinity Paper Mills, Dallas, Tex., is completing plans for the erection of its proposed new paper mill at Commerce, to have an initial capacity of 50 tons. The plant will specialize in the manufacture of writing papers, tissue, blotting and other papers. George W. Lull is president.

THREE RIVERS.—The Three Rivers Glass Co., recently organized, is perfecting plans for the erection of its proposed new local plant for the manufacture of flint glass bottles. The initial plant unit will cost about \$30,000, and is expected to be ready for occupancy in the fall. It will be supplemented by other plant buildings at an early date. John Finkbeiner is manager.

Virginia

ROCKY MOUNT.—The Vicama Mica Co. Inc., Hagerstown, Md., recently incorporated, is planning for the operation of mica properties in this section, as well as in North Carolina. The company will also produce feldspar and kindred products. Considerable equipment will be acquired for operations. John W. and J. R. Feldman, 3 Hamilton Row, Hagerstown, head the company.

RICHMOND.—The Pioneer Products Co., recently incorporated with a capital of \$1,000,000, will operate a local plant for the manufacture of rubber products. H. C. Wilder, Malone, N. Y., is president, and W. C. Faulkner, Richmond, secretary.

West Virginia

HUNTINGTON.—The Lambie Chemical Co. is arranging for increased production at its local plant, advancing to about 50 per cent of normal output. The company has recently been engaging at about one-half of this capacity. The working force will be increased by about 40 men, and particular attention given to color production. It is planned to develop the plant to its maximum in this latter line early in the fall. R. D. Lambie is president.

SCOTT DEPOT.—The Di Bella Glass Co., recently organized, will operate a local plant for the manufacture of glass products. The company is headed by H. H. Pine and E. A. Taylor, Scott Depot; and G. T. Pine, Charleston, W. Va.

Wisconsin

MILWAUKEE.—The Western Metal Specialty Co., 1919 St. Paul Ave., is completing plans for the erection of an addition to its plant to cost about \$40,000.

BLACK CREEK.—The Outagamie Limestone Co., 75 30th St., Milwaukee, has plans under way for the construction of a new limestone working plant in the vicinity of Black Creek, estimated to cost about \$200,000, with machinery. F. A. Mass is head.

New Companies

THE COROGO TANNING Co., Lynn, Mass., has been incorporated with a capital of \$50,000 to manufacture leather products. The incorporators are Saul L. Cohen and William J. Rose, Boston.

THE PAEPECKE PAPER MILLS Co., 111 Washington St., Chicago, Ill., has been incorporated with a capital of \$50,000 to manufacture paper goods. The incorporators are Walter P. Paepcke, R. L. McClelland and E. A. Lang.

THE CLEANING COMPOUNDS MFG. Co., New York, has been incorporated with a capital of \$25,000 to manufacture chemical compounds and kindred products. The incor-

I. White and T. N. Ripsom, 366 Madison Ave.

THE MINERALS REDUCTION CORP. OF AMERICA, Berwick, Me., has been incorporated with a capital of \$10,000,000 to operate reduction works for the manufacture of mineral and metal products. Thomas I. Hogan is president; Ralph W. Goss is treasurer.

THE MICA CO. OF CANADA, INC., St. Regis Falls, N. Y., has been incorporated with a capital of \$150,000 to manufacture mica products. The incorporators are O. H. Smith, C. J. Toohey and R. A. Reid. The company is represented by H. A. Ross, Montreal.

THE EMPIRE LABORATORIES, INC., West New York, N. J., has been incorporated with a capital of \$200,000, to manufacture chemicals and chemical byproducts. The incorporators are Jacob J. Storz, Frederick K. Lane and M. F. Curry, 595 Jefferson St.

THE ENO RUBBER CORP., Los Angeles, Cal., has been incorporated with a capital of \$20,000 to manufacture rubber goods. The incorporators are Roy R. Musser, George W. Eno and William M. Morse. William Morse, Jr., California Bldg., represents the company.

THE CENTRAL ILLINOIS PETROLEUM CO., 1703 B'way., Mattoon, Ill., has been incorporated with a capital of \$200,000 to manufacture petroleum products. The incorporators are Daniel S. Campbell, Thomas M. Stanbury and William D. Jones.

THE ESSENTIAL MATERIALS CO., New York, has been incorporated with a capital of \$100,000 to manufacture dyes, chemicals and affiliated products. The incorporators are G. Lau, L. H. Wallace and F. T. Com-moss. P. H. Delehanty, 115 B'way., represents the company.

THE NATIONAL REFRACTORIES CORP., New York, has been incorporated with a capital of \$20,000 to manufacture refractory products. The incorporators are J. M. Devlin, A. M. Klupt and W. Bruchhausen. Duncan & Campbell, 189 Montague St., Brooklyn, N. Y., represent the company.

THE ATLAS DIE-CASTING CO., INC., Worcester, Mass., has been incorporated with a capital of \$200,000 to manufacture die-castings and other metal products. The incorporators are Arthur M. Brewster, Allan Robinson and Malcolm F. MacNeil, 25 Brighton Ave., Boston, Mass.

THE KING-CRAIG OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are John J. Craig, Los Angeles; James W. Reagan, Long Beach, Cal.; and Everett H. King, Inglewood, Cal.

THE WOODSIDE COLOR CORP., New York, has been incorporated with a capital of \$50,000 to manufacture chemicals, colors, dyes and kindred products. The incorporators are C. S. L. Tuynman, W. D. P. Evans and B. L. Blauvelt, 99 Nassau St.

THE JUMBO TILE WORKS, INC., Goldsmith, Ind., has been incorporated with a capital of \$50,000 to manufacture clay tile, bricks and other burned clay products. The incorporators are E. A. Teter, W. A. Parks and J. N. Russell, Goldsmith.

THE RAVENSWOOD PORCELAIN & GLASS CO., Ravenswood, W. V., has been incorporated with a capital of \$500,000 to manufacture glass, porcelain and other ceramic products. The incorporators are J. H. Camp and J. W. Hall, Ravenswood.

THE ADAMS OIL & COMPOUND CO., 549 West Washington St., Chicago, Ill., has been incorporated with a capital of \$20,000, to manufacture compounds, chemicals, oils, etc. The incorporators are Harry R. Adams, Philip R. Monson and Mont C. Adams.

THE BEAVER RUBBER MFG. CO., New York, has been incorporated with a capital of \$250,000 to manufacture rubber products. The incorporators are F. L. Minnigerode, C. M. Coryell and W. P. Kown, 50 Church St.

THE MARYLAND INDUSTRIAL ALCOHOL CO., Baltimore, Md., has been incorporated with a capital of \$700,000 to manufacture industrial alcohol products and other kindred specialties. The incorporators are Edward H. Hammond, R. Bennett Darnall and Harry E. Karr, Fidelity Bldg.

THE WESTERN SEABOARD OIL CO., Los Angeles, Cal., has been incorporated with a capital of \$300,000 to manufacture petroleum products. The incorporators are J. W. Lonn, W. S. McKee and W. C. Bramham, Los Angeles.

THE AREX PRODUCTS CORP., New York has been incorporated with a capital of \$7,750,000 to manufacture chemical products. The

company is represented by Arthur W. Britton, 65 Cedar St., New York.

THE STARR CHEMICAL LABORATORIES, 16 Lewis St., Newark, N. J., has filed notice of organization to manufacture chemicals and chemical byproducts. Jacob Starr, 347 South 11th St., heads the company.

HULL & HULL, INC., Tampa, Fla., has been incorporated with a capital of \$50,000 to manufacture burned clay products. A. G. Runyon is president; Randall Bell, secretary-treasurer, both of Pensacola, Fla.

THE CARPENTIER CHEMICALS, INC., 175 West Jackson Blvd., Chicago, Ill., has been incorporated with a capital of \$10,000 to manufacture chemicals and chemical byproducts. The incorporators are O. T. Carpentier, Edward J. Hess and M. G. Eckersberg.

THE FEDERAL CHEMICAL CO., Nitro, W. Va., has been incorporated with a capital of \$250,000 to manufacture chemicals and chemical byproducts. The incorporators are John V. Ray, C. P. Miller and W. D. Payne, all of Charleston, W. Va.

THE NATIONAL ZINC CORP., New York, has been incorporated with a capital of \$300,000 to manufacture zinc and other metal products. Morris Stein, 945 Aldus St., is the principal incorporator.

THE KERO CHEMICAL CORP., Bay Shore, L. I., has been incorporated with a capital of \$300,000 to manufacture chemicals and chemical byproducts. The incorporators are C. Young, C. V. Reeve and H. W. Barto. F. J. Knorr, Albany, N. Y., represents the company.

THE L. V. S. SOAP CO., Gloucester, N. J., has been incorporated with a capital of \$125,000 to manufacture soap and kindred products. The incorporators are George Link, William J. Van Meter, Gloucester; and Spencer Simpson, Camden.

THE CHAMPLAIN VALLEY OIL CO., Plattsburg, N. Y., has been incorporated with a capital of \$50,000 to manufacture oils. The incorporators are O. L. Trembly, G. P. and R. A. Sharron, and B. F. Feinberg, Plattsburg.

THE RENFRO-JUSTUS PAINT CO., Brownwood, Tex., has been incorporated with a capital of \$10,000 to manufacture paints, oils, etc. The incorporators are J. F. Renfro, C. B. Justus and O. J. McInnis.

THE HANOVER BRICK MFG. CO., Morristown, N. J., has been incorporated with a capital of \$100,000 to manufacture bricks, with plant at Whippany, near Morristown. The incorporators are Richard W. and Jesse L. McEwan, and Charles W. Ennis, 3 Elm St.

THE CALIFORNIA PAINT & SHELLAC CO., Los Angeles, Cal., has been incorporated with a capital of \$20,000 to manufacture paint, shellac and kindred products. The incorporators are C. M. Berry, J. H. Weaver and G. S. Hinson. The company is represented by Alfred Barstow, 600 Kerckhoff Bldg.

THE BOVING MFG. CO., 111 East State St., Trenton, N. J., has been incorporated with a capital of \$100,000 to manufacture tiles and other ceramic products. The incorporators are Christian O. Osterberg, Paul C. Boving and Charles J. Falcey, Trenton.

THE QUINLEY MAGNESIA CO., Cortland, O., with an authorized capital of \$100,000 of 8 per cent cumulative preferred stock and 2,000 shares of no par value common stock, has been incorporated, with J. C. Quinley, L. A. Kirtland and others as incorporators. The company will erect a plant on the Erie R.R. at Cortland for the manufacture of asbestos and magnesium products. An initial daily output of 4,000 lb. of magnesium carbonate is expected by July 1 from the first unit. The product manufactured will be largely for drug and rubber trades and for locomotive lighting, pipe covering, et cetera.

THE MARVELLUM CO., Holyoke, Mass., has been incorporated under the laws of Massachusetts with a capital of \$165,000 and has leased manufacturing space in the Holyoke Valve and Hydrant Bldg. It will start manufacturing a line of specialty cover papers according to a new coloring process. The officers are George Senseney, F. C. Haywood and Russell Bracewell.

The B. & M. Oil Co., Los Angeles, Cal., has been incorporated with a capital of \$500,000 to manufacture petroleum products. The incorporators are J. M. Brown, Long Beach, Cal.; F. N. Crippen, Pasadena, Cal.; and S. E. Meserve, 417 Union Oil Building, Los Angeles.

The Carbonite Mfg. Co., 324 Stephen Street, Belleville, N. J., has filed notice of organization to manufacture carbon specialties. William H. Moulton heads the company.

Capital Increases, Etc.

THE EASTMAN SALT PRODUCTS CO., Saginaw, Mich., has filed notice of change of name to the Saginaw Salt Products Co.

THE MONONGAH GLASS CO., Fairmont, W. Va., is arranging for an increase in capital from \$1,000,000 to \$2,500,000. R. T. Cunningham is secretary.

THE HARNER OIL & REFINING CO., St. Paul, Minn., a Delaware corporation, has filed notice of change of name to the Harner Oil Refining & Mining Co., at the same time increasing its capital from \$2,000,000 to \$10,000,000.

THE UNITED ALLOY STEEL CORP., 165 B'way., New York, has filed notice of change in capital to an active amount of \$9,525,000, and preferred stock to the value of \$3,300,000. The company recently took over the United Furnace Co., and the Berger Mfg. Co., Canton, O.

THE INDEPENDENT OIL CO., Decatur, Ill., has filed notice of increase in capital to \$50,000.

Coming Meetings and Events

AMERICAN CHEMICAL SOCIETY, THE SOCIETY OF CHEMICAL INDUSTRY and the American Section of the latter society will hold a joint meeting in New York, Sept. 6 to 10.

AMERICAN ELECTROCHEMICAL SOCIETY will hold its fall meeting in Lake Placid, N. Y., Sept. 29 and 30, and Oct. 1.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS will hold its spring meeting June 20 to 24 at Detroit. Industrial excursions will be made to Ann Arbor, Saginaw, Midland and Bay City.

AMERICAN IRON AND STEEL INSTITUTE will hold its nineteenth general meeting in the Hotel Commodore, New York, on Friday, May 27. There will be three sessions: A forenoon session beginning at 10 o'clock daylight saving time (9 a.m. eastern time); an afternoon session at 2; and a banquet in the evening at 7.

AMERICAN LEATHER CHEMISTS ASSOCIATION will hold its eighteenth annual meeting at the Hotel Ambassador, Atlantic City, June 9, 10 and 11.

AMERICAN MINING CONGRESS AND NATIONAL EXPOSITION OF MINES AND MINING EQUIPMENT will hold its twenty-fourth annual convention in the Coliseum, Chicago, Oct. 17 to 22.

AMERICAN OIL CHEMISTS' SOCIETY (formerly the Society of Cotton Products Analysts) will hold its twelfth annual meeting in Chicago May 16 to 17. Headquarters will be at the Congress Hotel.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS will hold its spring meeting at the Congress Hotel, Chicago, May 23 to 26.

AMERICAN SOCIETY FOR STEEL TREATING will hold its third annual convention and exhibition Sept. 19 to 24 at Indianapolis.

AMERICAN SOCIETY FOR TESTING MATERIALS will hold its 1921 annual meeting in the New Monterey Hotel, Asbury Park, N. J., during the week of June 20.

THE NATIONAL EXPOSITION OF CHEMICAL INDUSTRIES (SEVENTH) will be held during the week of Sept. 12, in the Eighth Coast Artillery Armory, New York City.

NATIONAL FERTILIZER ASSOCIATION will hold its twenty-eighth annual convention at the Greenbrier Hotel, White Sulphur Springs, W. Va., the week beginning June 20.

NEW JERSEY CHEMICAL SOCIETY holds a meeting at Stettens Restaurant, 342 Broad St., Newark, N. J., the second Monday of every month.

SOCIETY OF CHEMICAL INDUSTRY (BRITISH) at the invitation of the Montreal section will hold its annual meeting in Montreal and other Canadian cities during the week of Aug. 29, 1921. Details will be printed in this magazine from time to time.

STAMFORD CHEMICAL SOCIETY, Stamford, Conn., holds a meeting in the lecture room of the local high school on the fourth Monday of each month; except June, July, August and September.

The following chemical societies will meet at Rumford Hall, Chemists' Club, New York City, as follows: May 13, Société de Chimie Industrielle, joint meeting with American Chemical Society, Society of Chemical Industry and American Electrochemical Society; May 20, Society of Chemical Industry; June 10, American Chemical Society.

Number 20

Chemical Industry and The Department of Commerce

IN THE brief time that Mr. HOOVER has been Secretary of Commerce he has given ample evidence of his desire so to conduct the Department as to be of maximum service and benefit to industry. As far as we can observe, his activities do not contravene the expressed policy of the Administration to have "more business in government and less government in business." The function of the Department of Commerce is not to regulate industry but to serve it; and Mr. HOOVER's name is synonymous with service.

Three bureaus of the Department are of particular interest to the chemical industries, namely, the Bureau of Standards, the Bureau of the Census and the Bureau of Foreign and Domestic Commerce. Significant of Mr. HOOVER's estimate of the importance of these bureaus is the fact that in the organization of his department he plans to give them his personal attention. Further to study the relation of these bureaus to industry and expand them as aids to business Mr. HOOVER has selected as his personal assistant F. M. FEIKER, vice-president and chairman of the Editorial Board of the McGraw-Hill Co. Mr. FEIKER's engineering training, knowledge of industry and sense of publicity qualify him exceptionally for this work. The extent to which these three bureaus can serve depends largely upon the support received from Congress, and we believe that the chemical industry can well support the request of the Department for an appropriation of about \$600,000 which is now before the Committee on Appropriations. A favorite method of comparison of all appropriations is to relate them to the huge sums requested for the support of our military establishment. In these terms Mr. HOOVER's request is for a sum said to be equivalent to the cost of only one battalion of troops for one year.

In planning the work of the bureaus mentioned, three points of view are being kept in mind: First, the broad problem of building up a closer contact between the Department and industry; second, the necessity of developing fuller statistical data; and third, a study of industry to discover those areas in which standardization and simplification can be applied to advantage and without detriment. Approximately \$250,000 is being asked for the purpose of building up a closer contact with industry. This will probably be done through the medium of industrial service committees within the Department, comprising perhaps a dozen groups of workers, each headed by a man familiar with the conditions of a particular industry. These industrial service committees will be advisory to the Secretary in determining what the Department can best do for the different industries. In improving the statistical service of the Department five items of prime importance will be considered: 1, statistics of production; 2, statistics of stocks; 3, the percentage activity

in an industry; 4, prevailing basic prices, and 5, the prompt issuance of a report so that the figures will be of current value. The third point of service—the matter of standardization and simplification—is one to which a considerable part of the requested appropriation, say \$350,000, probably will be devoted. Here again a series of industrial service committees will be the medium through which the problem will be attacked.

Our readers will learn with satisfaction that the Secretary of Commerce is in thorough accord with the program of economy to which the Government is committed and that he has not asked for new appropriations without first effecting economies within his Department in a sum aggregating several times the amount now requested of Congress. In view of this attitude and the evidence of careful study and planning for the expenditure of the money not only for the benefit of industry but largely under its own advice and direction, we feel quite justified in urging representatives of the chemical industries to support Mr. HOOVER's request for appropriations.

Professional Services Recognized In Proposed Classification

FAVORABLE recognition is given to professional men in the Government service by legislation introduced at this session of Congress by Mr. WOOD of Indiana and Senator SMOOT of Utah. This legislation provides for "an equitable system for the valuation of the services of civilian employees of the Government," and the professional workers are gratifyingly appraised in the terms of the proposed legislation.

If this Wood-Smoot bill becomes a law the junior-chemist grade will begin at \$1,860 and provision will be made for the higher technical positions up to salaries of \$7,500. The bill very frankly recognizes that it is impossible to define in words the ranks or qualifications of different professional positions. Indeed it uses almost identical language for all of the places in scientific work from \$2,500 to \$7,500 per year and says regarding them that "the distinction between grades is based upon differences in the training and experience required in the work."

We are prone to think that our national legislators are slow to recognize the urgent necessities of professional positions. In the past they doubtless have been. But this is a most encouraging sign, and one which industrial executives employing professional chemists can do well to emulate. The term "chemist" is so broad in meaning that arbitrary fixing of salaries for those qualified for the title is wholly impossible. Let us hope that Congress will officially confirm the proposed plan of Government classification and that our industrial organizations as well will recognize that "distinction between grades is based upon differences in the training and experience required in the work."

A Great Obligation

SOME very interesting statistics have lately come to light. In 1890 there were about 200,000 pupils attending secondary schools in the United States. That means children, or, rather, adolescents who are engaged in courses beyond the eight years required. Whether these are public high schools, or the four upper forms of boarding schools such as Exeter or Andover, or military academies, or what we call private and our British cousins call public schools such as St. Paul's or Groton, or Roman Catholic institutions, makes no difference. It represents the standard four years of education following the grammar school course and leading to matriculation in colleges and the higher institutes of technology. By 1900 there were upward of 900,000 such pupils in the United States. Today the number is over 1,600,000. This number represents more than one-half of the young persons in the world who are enjoying secondary education.

What does it mean? Our population has not increased in any such ratio. It tells us that Young America wants to learn.

In the United States Army a series of continuation schools has been introduced. These have to do with trades rather than with professions, but it represents study. Every prescribed occupation is analyzed into a definite number of things that a plumber, a carpenter, a mason, etc., must know how to do. The courses are definitely laid out, and more than 60,000 United States soldiers are now studying at these various trades.

But what does it all mean? The curricula are hardly satisfactory; many school systems still languish in the throes of politics; we do not respect teachers or give homage to the few men and women who are by nature exceptionally gifted to practice the greatest of all arts, which is that of teaching; we quarrel among ourselves as to whether somebody shall read a chapter from the Bible or not, but we do not bother about ethics—and yet there are over a million and a half students eager to learn, and “we leave it to the authorities.” The authorities are usually politicians, and what they are after is votes.

What are these young people learning, and how shall we meet them? Will they learn that it is better to do work well than to tell somebody else to do it? Here is a great thesis in the philosophy of life. Every real artist knows the joy of work, and so does every true mechanic who has the privilege of liberty. Now, liberty is a much more restricted concept than most of us think it is. There is no such thing as absolute freedom. But why should we not enjoy such liberty as we have?

There is the man, for instance, who works eight hours a day. When the whistle blows or the bell rings his task is finished. Eight or nine hours is all the time he wants for sleep, and the rest is his. If he loves the arts or music or literature or is interested in the sciences, he has the opportunity not only to improve his mind but to enjoy life. He can do what he wants to do under his own rights and privileges. He is a remarkably free man. The superintendent of the works, on the other hand, the man who commands, is little more than a slave. He has given hostages for his position and salary. His work is never finished. He is engaged in administration, and administration is intellectual slavery. He can't

do what he wants to do, because something is always going wrong—if he is competent and has the wit to see it. The only leisure he knows is rest; detective stories, movie shows and musical comedies are the substance of his recreation. He can't develop his mind beyond the interests of the corporation which he serves. He lives an unenviable life.

Now, the question which intrigues us is whether, with this increased education, our young people will learn this fact. Ordinary common labor today is as remunerative as, and even more so than, two of the learned professions: Teaching and divinity. It pays better than the early years, as a rule, of engineering or law or medicine. It is a dignified occupation to work with our hands. And if we are gifted with sanity and a useful mind, we can find contentment in it. But scorn is the enemy of contentment, and those of us who employ others will need to bear this fact in mind as keenly as those who work for us will sense it.

It is a proud thought to consider half of the high school pupils of the world as being in the United States. But unless we meet it right it may be anything but a blessing. It confers a new and greater obligation on those of us who lack the greater freedom because we direct affairs.

Technology Brings Youth to Industry

Every Youthful Minute is a Precious Inch of Gold!

ARGUMENTS between executive and sales manager are rather common occurrences at all seasons of business, but they happen with increasing frequency during the late afternoons in these depressing times. They are not always fruitful of so much good as in the following instance, with quotations practically verbatim:

PRESIDENT—But we can't quote as low a price as the Burnt Clay Co. It costs us more than that to make the stuff.

SALES MANAGER—Certainly it does. Why? Because you are using antiquated methods in producing the ware. They date back beyond the time of the Mound Builders. You are mixing by “feel,” hand-molding standard ware, conveying by wheelbarrow and burning the clay by the “expert's” eye. Why, your plant man told me the other day that he had pyrometric cones in the office “in case he ever needed them.” And if you showed him a recording pyrometer he'd think it was an attachment for a steam engine or an automobile. If your plant were operated with a definite knowledge of materials you are handling and producing you wouldn't have to fear anybody's price.

PRESIDENT (With frown, grin and frown)—That's enough, young fellow. If you know so much about this new scientific-stuff-in-industry business, I'm going to give you a chance to run the plant for a while, even to long-necked bottles, glass-covered scales and the rest of the tricks.

The upshot of this conversation was that the sales manager shortly became superintendent of plant with considerable authority to make changes. Fortunately he was a man with some intimate knowledge of the business all along the line from the clay pits to marketing the product. He knew the old way, but had gained young ideas.

This actually took place several months ago and if the reader could take a walk through the works with him now, see the changes made and in the making; note the economies effected by rearrangement of operations, the reasonable amount of new equipment installed for further cost-per-unit decreases and listen to his discourse on plans for a future scientific control laboratory to get uniform quality of product, he would realize that

the president acted with canny foresight when he gave this chap plenty of leeway.

The next best thing to being a live one is for a man to realize he's a dead one. It is not hard to see why this executive has attained a place in his chosen business. When it had developed beyond the knowledge of his time, he called in youth to carry it on, wherefore he should enjoy the progress and incidentally a few more "inches of gold."

Labor Unions and Industrial Decay

REPRESENTATIVES of the labor unions before the Railroad Labor Board have made the claim that the railroads are wasting at least \$1,000,000,000 a year through mismanagement, and assert that wages should not be touched until all the leaks are stopped. There is an inconsistency in the position, in that the claim has likewise been set up that the ability of the railroads to pay wage rates should not be considered. The *Railway Age* points out the absurdity of the \$1,000,000,000 claim in another way, observing that last year's railroad operating expenses were \$6,300,000,000, of which \$4,000,000,000 would be absorbed by wages, leaving \$2,300,000,000 out of which the \$1,000,000,000 would have to be saved, so that the other expenditures would have to be reduced by about 45 per cent.

The United Mine Workers have a wage scale, arranged when all costs and prices were practically at their peak, and which was high even for those conditions. This scale is signed to April 1, 1922, and apparently is not susceptible of modification meanwhile.

Wages in the building trades are very high, for a day's work or a week's work, and they are much higher still on the basis of the quantity of work done by the artisans in a day. The usual dates for annual settlements of the scales in the building trades are May 1 and June 1, and very few reductions have been made. In several districts strikes are now on.

The average observer of business conditions, if he gave no thought to the fact that the railroad workers and the workers in the building trades are well organized, would undoubtedly say that two of the prominent things that are retarding a return of industrial activity are the high costs of railroading and of building. The cost of mining coal is also very high, but that fact receives little attention simply because people do not want coal just now in any quantity.

If from the total of labor unionism in the United States there be subtracted the unions on the railroads, in the building trades and in the coal mines there is very little left. Of all the workers in the country only between 10 and 15 per cent belong to unions, and if the three monopolies are subtracted only a very small per cent is left.

These three classes of unionism must be taken as representing what unionism means. They represent conditions where unionism is successful. If now we should estimate all the work that should normally be done in the United States and allot it by percentages to crafts, the proportion allotted to coal mining, building and operation of the railroads would be far less than the percentage of wage drawers that are now in these lines of activity.

What does this mean but that these men are not doing their share of the work of society? They are drones, relatively speaking, supported in part by the

rest of the workers. It is not so much that they receive too much money for a day's work as it is that they do not render a full day's work. In this respect they may not differ from their non-union associates, except that they have the power of organization to enforce their ideas. But suppose that unionism should spread and the attempt be made to fasten the principle upon all lines of work. Who would be left to pay the bill? What would be the result of the effort?

The answer to the question was given by Judge GARY at the recent annual meeting of the stockholders of the United States Steel Corporation. It being the twentieth anniversary, Judge GARY reviewed the "principles and policies" of the corporation. He dwelt upon its attitude in being so strongly committed to the "open shop," saying: "The 'natural and certain effects of labor unionism are expressed by three words: Inefficiency; high costs.'" And again: "I firmly believe complete unionism of the industry of this country, as attempted, would be the beginning of industrial decay." Perhaps; and yet maybe no more so than would be true of complete domination by capital. However, Judge GARY has given the answer to the question what would occur if the principles and practices of the railroad unions, the building trades unions and the United Mine Workers were forced upon the entire body of workers. There would be no one left to pay the bill.

Germany Bows To the Inevitable

WITH Germany's acceptance of the demands of the allied governments she assumes a burden which her people can lift only through persistent effort. Ever since the Armistice there has been considerable speculation as to when Germany might recover her commercial status among the world's nations and how that end would be attained. The matter is of more than ordinary interest to the chemical industry because of Germany's former pre-eminence therein. It is timely, therefore, to speculate on the prospects. Considering the German's character it seems likely that under stress of fulfilling the terms of the Peace Treaty he will develop a degree of efficiency and excellence in production such as the world has never seen. In this he will be aided by the government, which will subsidize him through food sold below cost and other similar devices. The consequence may be that for a time the German will appear to be rapidly regaining his lost industrial prestige, with proportionate menace to the industry of our own and other countries. With respect to ourselves, however, the other side of the picture is that the German has no conception of quantity production such as we commonly see in the United States; nor has he a large domestic market for the consumption of his product. Added to this is the inevitable fact that some day he must reap the real harvest of government subsidy of business and come face to face with the necessity of competing with the other nations of the world on an equitable economic basis. With anything like maximum production in this country and with a large and increasing domestic market the United States has little or nothing to fear from German competition. This will be true, however, only by increasing efficiency of production, because we will be forced to meet competition under a low standard of living that must continue in Germany and on the Continent for at least a generation.

Readers' Views and Comments

The Valentiner Vacuum Process

To the Editor of Chemical & Metallurgical Engineering

SIR:—While I was absent from the country your résumé of my extemporaneous talk on nitric acid before the Delaware Section of the American Chemical Society appeared in the March 9 number of *CHEMICAL & METALLURGICAL ENGINEERING*, page 443. In this abstract I note the statement on page 445 that "the Valentiner vacuum process proved to be a failure commercially."

Though I may have conveyed this impression in my talk, it was far from my intention to do so, because this process is operating successfully in this country and also in Germany today. What I wished to bring out was that the vacuum was originally employed to enable the retort reaction to be carried to completion at a lower temperature, but this caused foaming and a tendency for the soda to float on the top of the charge, unduly lengthening the time of distillation; consequently the device was adopted of throttling the gases at the exit of the retort (see U. S. Pat. 920,224, to F. S. Valentiner), thus putting the retort under pressure but keeping the condensation and absorption systems still under a vacuum.

This, I pointed out, was exactly the opposite of what is desired theoretically to obtain the best results.

Condensing and absorbing under a vacuum does, however, produce a water-white acid, and for manufacturers of this grade of acid the larger equipment and the additional pumps, etc., of the Valentiner process are doubtless justified. For ordinary commercial grades of acid for nitrating purposes it seems doubtful, however, whether the Valentiner process can compete with the ordinary distillation at atmospheric pressure from the cost standpoint.

Treatment of Acid and Alkali Burns

To the Editor of Chemical & Metallurgical Engineering

SIR:—In his instructive article on "The Treatment of Acid and Alkali Burns," printed in your issue of April 27, Dr. A. K. Smith does not mention hydrofluoric acid; though he does mention the perhaps less common and certainly less dangerous chromic acid, including it inadvertently under "caustics."

During a long experience in charge of manufacturing operations I have had frequent opportunity to observe the effects of various acids on living tissues and there is, I think, none more dangerous than hydrofluoric in the higher concentrations. This acid has, in some cases at least, the peculiar and insidious property of inducing something like a partial anæsthesia in the tissues with which it comes in contact. At first there may be only a period of minor irritation, of duration and intensity varying with the individual but which frequently causes the careless or uninstructed to delay or neglect proper prophylaxis. Later comes agonizing pain, with tissue destruction and a wound of unhealthy character, very slow in healing. With deference to Dr. Smith's greater technical knowledge of this subject, I must say

that I think I have observed in acid burns a poisonous effect extending beyond the initial destruction of tissue. This effect seems most marked with hydrofluoric, less so with nitric, and least with sulphuric. An additional malignant property of hydrofluoric is the effect of its vapor, especially in contact with the finger nails. Hours of misery have followed prolonged holding of a rubber stopper wet on the lower end with the concentrated acid; and following one occasion on which I got a particularly bad dose of the vapors on the fingers blood extrusions began to grow out under two finger nails after a few days. I have seen workmen pass periods of profane discomfort after handling barrel bungs with unprotected fingers, though there were no visible effects on the skin.

Yes, "hydroflu" is surely worthy of a place in Dr. Smith's list. As a destructive fluid I place it second only to some of the home-brewed "hooch" with which our western Pennsylvanians corrode their interior mysteries. I used to make the stuff—the hydrofluoric—in Long Island City, but even along Newtown Creek it was found unbearable, and we were chased to a site on the Jersey marshes, bounded on one side by the Hackensack River and on the three others by a population of scientific workers for whom all metals had magnetic properties and were convertible into various forms of CH_3OH —all, that is, but the lead of our HF equipment. That was as safe as soap in Petrograd; and the merry villager whose favorite outdoor sport was to shatter the unprotected carboy of vitriol or nitric into smoking ruin with an indigenous brick made devotional gestures as he passed—on the far side of the road—the ranked lead boxes of hydrofluoric awaiting shipment.

Seriously, though, it is desirable to advertise that this widely used and indispensable acid is highly corrosive to tissues, and requires special precautions in handling because of the unusual properties already mentioned.

One other word might supplement Dr. Smith's advice. That is the necessity, where large quantities of strong sulphuric acid have reached skin and clothing, of using the largest possible quantity of water and continuing its application for a considerable time. If the acid has saturated any part of the clothing, only a copious and continued drenching—preferably an immersion—will keep the burn from being seriously intensified by the heat produced from contact of water and acid.

Porcelain Enameling Furnaces

To the Editor of Chemical & Metallurgical Engineering

SIR:—In your issue of April 6 you published a letter from Francis A. J. FitzGerald concerning electrically heated porcelain enameling furnaces. It may be of interest to your readers to know that in the April and June numbers of the *Journal of the American Ceramic Society* there will be published two papers describing commercial installations of furnaces of this type.

Urbana, Ill.

Award of the Nichols Medal to Gilbert N. Lewis

Proceedings of Meeting—Appreciation of Medalist and Personal Reminiscences—Address on Color and Chemical Constitution With Regard to the Subatomic Structure and the Nature of the Electron Bond

THE Nichols Medal was presented Friday evening, May 6, to Dr. Gilbert N. Lewis, of the University of California, for the best original paper published in any of the journals of the American Chemical Society during the year 1920, and in the judgment of the jury this best paper was the one entitled "The Third Law of Thermodynamics and the Entropy of Solutions and of Liquids," by the recipient and G. E. Gibson.

An Appreciation of the Medalist

BY ARTHUR B. LAMB

I am very glad of my opportunity this evening to say something about the achievements and personality of G. N. Lewis. As we have him with us here in the flesh, I will endeavor to make my remarks about him seem as little like an obituary as possible; I have come, not to bury Cæsar, but laud him.

My acquaintance with him began eighteen years ago, when as a graduate student at Harvard I listened to his lectures on electrochemistry and thermodynamics. Lewis had graduated from Harvard College several years before, in 1896, had taken his Ph.D. in two years of graduate work, had taught a year at Phillips Exeter Academy, and was then back at Harvard as an instructor. In these lectures Lewis accomplished the real *tour de force*, of kindling our interest in and enthusiasm for such subjects as entropy, free energy, and a special thermodynamic function all his own, which he had christened "fugacity." His lectures were remarkable in still another respect. He covered thoroughly an enormous amount of ground. Throughout his lectures Lewis kept pacing back and forth across the platform, covering miles at breakneck speed. From Harvard Lewis was called to a professorship at the Massachusetts Institute of Technology, and a few years later left to be head of the department of chemistry at the University of California.

NATURE OF CHEMICAL AFFINITY

At the outset I must call your attention to a striking coincidence. Sir Isaac Newton in his "Principia" says: "There are agents in Nature able to make the particles of bodies stick together by very strong attractions. And it is the business of experimental philosophy to find them out." Newton thus recognized and propounded the problem of chemical affinity, and this is the very problem which has been the main object of attack in the many brilliant researches of our medalist, Gilbert Newton Lewis, in part therefore at least the namesake of his great predecessor.

Evidently one way to study the nature and magnitude of chemical affinity is to find out the amount of heat and other forms of energy which it can produce. Lewis in his doctor's thesis and in his first independent published article made important advances in this direc-

tion. He developed on thermodynamic grounds a general equation of chemical affinity and showed how in favorable cases by its means the extent of a chemical reaction could be computed from thermal and physical data. More important still, he showed in this article for the first time that a complete solution of this problem required a knowledge of certain then indeterminate constants characteristic of the particular varieties of matter under consideration. It was a study of these very constants which later led others to formulate what is now called the Third Law of Thermodynamics, which Lewis himself has further clarified in the paper for which the Society is now conferring the Nichols Medal—namely, "The Third Law of Thermodynamics and the Entropy of Solutions and of Liquids."

Between this first paper and this last one Lewis has published a score and more of articles dealing with the chemical affinity of a great variety of substances. Certain of them have been particularly important—for instance, his determination of the free energy of formation of water at room temperatures, and also his determination with Dr. Kraus for the first time of the potential of the sodium electrode.

RELATIVITY AND A SYSTEM OF VECTOR ANALYSIS

Lewis has not been content to confine his studies even to so broad a field as chemical affinity. He was practically the first American to discover Einstein. As far back as 1909 he published a paper on "Relativity" in which he developed a new system of vector analysis which facilitated the further study of this subject, and later he developed a wholly new system of non-Euclidian geometry and vector analysis which appears to offer many advantages in the solution of recondite mathematical problems. One can thus see that Lewis in these papers has gone over from the field of chemistry into what is pure mathematics. In this connection it is interesting to point out that he never took any courses in mathematics higher than analytical geometry. He studied the calculus and higher mathematics by himself as a form of recreation.

MILITARY ACTIVITIES

As illustrating still another side of Lewis' mentality and personality, I want to tell a little about his activities during the war. He went to France in the first months of 1916 with Colonel Bacon's contingent in the Chemical Warfare Service. General Fries sent him very soon to act as observer for the Chemical Warfare Service with the Fifth British Army. Lewis had hardly arrived there when the Germans launched their great offensive against that army. It was a thrilling experience, but a valuable one. Lewis withdrew in good order along with the rest of the army, but the closeness of the call may be judged from the fact that he is said to have left his Sam Browne belt behind him. But this did not prevent Lewis from accomplishing

his purpose. On his return he presented a report to General Fries on the progress of this battle and its significance and lessons from the chemical warfare point of view, which General Fries told me was the most suggestive report even from a strictly military point of view of this engagement which he had read. Up to this time General Fries had been unable to secure a satisfactory chief for the Defense Division of the Chemical Warfare Service. Two colonels in the regular army had held this position, but the problems to be faced were so novel and so foreign to their training and education that they had been unsuccessful. General Fries appointed Lewis to this position and he served with conspicuous success.

PERSONALITY

Finally, I cannot close without saying something more specific about the personality of our medalist. Though his intellectual and professional interests are prodigiously highbrow, as I have shown you, he is nevertheless just as keen as the rest of us about more ordinary things. He plays a dashing and successful game of three-handed bridge, where his venturesome instinct finds free scope, but at chess these very tendencies often prove his downfall. With or without the stimulus of ethyl alcohol, in any company he is the focus of the liveliest discussion and the center of the merriest group. Indeed, to describe this side of his personality I cannot do better than adopt the phraseology of the day, though perhaps it is already that of yesterday. Lewis is a "regular fellow."

Some Personal Reminiscences

BY JOHN JOHNSTON

I also am very glad of the opportunity to say a few words in appreciation of Gilbert Newton Lewis, whom you have chosen to honor by award of the Nichols Medal this year. But I am in somewhat of an embarrassment because I find that the things I had planned to say have already been said by my predecessor. We agreed at the Rochester meeting that he should talk more about the thermodynamic papers and I was to talk more about the others; but I find that he spread over into my assignment, and I didn't know that until at dinner tonight when we exchanged papers, I having written down what I proposed to say, coming on the train today, and Mr. Lamb having done likewise. But perhaps you will believe us more when we both agree, because you remember that— isn't it in "Alice in Wonderland" that someone there says, "What I say three times is true"? Therefore, what two different people say once each ought to be as true as what any common person says three times.

I met Mr. Lewis for the first time on the day that I first arrived in Boston in 1907. He took me to lunch, introduced me to my first cocktail as such—or perhaps I should say introduced my first cocktail to me, and ordered among other things corn on the cob, which I had never seen before—I think partly in pursuance of a scientist's curiosity to see just what would happen. This was but the first of very numerous meetings during the year that I spent in Boston. I also know about his proficiency at auction bridge and can confirm exactly what Mr. Lamb said about it. These frequent meetings with him led me to form a very high opinion of him, both as a scientist and as a companion and friend, and nothing since has given me reason to modify that opinion except perhaps to make it higher than it

was. He doesn't really fit in well with the conventional idea that a scientist, and particularly a scientist who is absorbed in the kind of fundamental questions that he is, is a cloistered type of highbrow who is unable to enjoy the good things of life and unfitted for participation in the world's work. As to the former—his ability to enjoy the good things of life—I could bring forward the testimony of his very large number of friends. As to the other—his capacity to take effective part in the world's work—that is well known.

Indeed he is in the proper sense of the word devoted to science and in particular to a study of the simplest terms in which we may express the multiplicity of chemical phenomena. And he works because he is possessed of an absorbing curiosity to know just what is what, possessed of a desire to correlate things apparently diverse, and from such correlation to be in position to predict new things. With this perhaps goes the fact that his papers are models of concise exposition—so concise indeed that many readers, I believe, fail to grasp their true significance or to see that some remark of his may have implied a very great deal of work and thought in order to be able to make it at all. And with this perhaps also goes the further fact that he is less interested in questions of credit and priority than that we should reach a satisfactory and thoroughly consistent explanation of the phenomena.

PUBLICATIONS

I have left myself little time in which to say anything specific about Mr. Lewis' other lines of work. On looking over the list of his published papers I find that the great majority of them were either about thermodynamics directly or so closely related to it that I felt I should leave them to Mr. Lamb. The others, though, are no less important. There are the papers on the theory of relativity, published ten years ago, to which Mr. Lamb alluded, which were written at a time when that theory had not attracted the attention now drawn to it. And there is one which brings in the subject of vector analysis, which Lewis taught himself in order to be able to attack the problem as he thought it should be attacked. Related to this are later papers on the quantum theory and on a system of ultimate rational units—e.g., to take the speed of light as the rational unit of velocity, and the charge in the electron as the unit of electricity.

VALENCE THEORY

His work which is now probably most familiar to you is that on valence theory. His first paper on this general topic appeared in the *Journal* of our Society in 1913. In it he emphasized the distinction between what he called polar and non-polar compounds, this distinction being roughly the same as that between inorganic and organic compounds, the polar compound being typified by a salt such as sodium chloride, NaCl, the non-polar by a substance such as methane. And he pointed out that these differences may be regarded as depending upon the magnitude of the constraints with which the valence electrons are held. Of course it would take too long to go further into that here, and probably you are all familiar enough with it, so that it would be beside the point for me to go into it.

In 1916 his next paper on the valence theory appeared. That was called "The Atom and the Molecule." In this paper he proceeds to extend this idea expressed in the previous paper and outlines the theory of the

cubical atom, the basic figures to which, it may be noted incidentally, are taken from a memorandum dating from 1902, which is therefore fourteen years before this particular theory was published in the *Journal*. He has since published two other papers dealing with this theory which are less well known, both published in 1917 (one in *Science*, the other in the *Proceedings* of the National Academy), and then in 1917 the war came on, and for a couple of years he was away from all writing of theories. The brilliant advocacy of these ideas by Langmuir and his exemplification and extension of their utility has made them familiar to all who take a real interest in our subject.

Presentation

BY JOHN E. TEEPLE

We come now to the presentation of the Medal itself. This has a significance more than we are accustomed to attach to such ceremonies. To the chemist working steadily and systematically, sometimes brilliantly, to advance his science, no appreciation is so welcome as that of his fellow chemists, men who understand what he is doing, what difficulties he encounters, what patience, skill, perserverance and calm analysis are necessary to surmount them and what bearing his work has on the progress of the science as a whole. On the other hand, the judgment of his co-workers regarding a fellow chemist does not go far wrong. Sometimes in a burst of enthusiasm the jury may pin a medal on a man whose work more mature deliberation may indicate to be not quite up to the proper standard. Sometimes, due to lack of knowledge of the man or interest in the subject, exceedingly high-grade work may be overlooked by a jury. Geniuses, as a rule, are not appreciated until a later generation, but in the long run the judgment of a man's co-workers is just, and an examination of the list of the recipients of the Nichols Medal to date shows a roll of honor. I feel that the jury, in selecting Dr. Lewis for the Medal tonight, have done themselves credit.

Dr. Gilbert Newton Lewis, on behalf of the New York Section of the American Chemical Society, it gives me great pleasure to present to you this beautiful William H. Nichols Medal for your original work on "The Third Law of Thermodynamics and the Entropy of Solutions and of Liquids," and I want to congratulate you personally and on behalf of the Society on this honor that has been conferred upon you.

Color and Chemical Constitution

BY GILBERT N. LEWIS

The science of color may be investigated from several points of view and presents different aspects to the physicist, to the physiologist or experimental psychologist, and to the chemist. The physicist is interested primarily in the properties of light while it is in transit, or, as we used to say before the luminous ether became unfashionable, the physicist is interested in the properties of the various types of ether waves. Frequently the phenomenon of light is compared with the phenomenon of sound, and the analogy is correct in this one respect, that both phenomena are characterized by oscillation or vibration or undulation—that is, with some sort of process of repetition, the period or the frequency of which manifests itself to our auditory or visual senses. Aside from differences of intensity, variations in this frequency are responsible for the variety of

the sensations produced through the ear and through the eye. It is this analogy which permits us to transfer the nomenclature of one phenomenon to the other. Thus we sometimes hear people speak of the *tone* of a color.

But while light and sound have in common this property of periodicity, there the resemblance ceases. Sound is produced in air or other material medium by the vibration of a body such as a tuning fork or a violin string, and the vibrations which are audible lie between the range of about 20 per second on the one hand and about 40,000 per second on the other—a range of about ten octaves. On the other hand, the general radiant energy of which light is a portion is produced only by the vibration of a body which is electrically charged. It travels through space even in the absence of any material medium, and that part of the whole gamut of radiant energy which is visible to the eye represents an enormous vibratory frequency—more than a million million oscillations per second.

THE VISIBLE ZONE OF RADIANT ENERGY

The sound produced by a drum differs from the purer tone of a more highly developed musical instrument in that it emits a jumble of many such tones simultaneously, and such a jumble of tones we call a noise. Like such a noise ordinary light is a mixture, representing vibrations of a great variety of frequencies. By means of a prism it is possible to analyze white light into its component tones, and thus we obtain the spectrum, where at every point there is a definite spectral color corresponding to a perfectly definite frequency. The rays that the eye cannot perceive may be seen by the camera and other devices which have made it possible to extend the spectrum and to study radiant energy beyond the limits of visible frequency, and thus investigate the ultra-red on the one side and the ultra-violet on the other. Indeed we now know that all the phenomena of radiant energy, beginning with the low frequencies of wireless telegraphy through the ultra-red into the visible out into the invisible ultra-violet, and from there on out to the region of X-rays, we are dealing with a single phenomenon, varying only in rate of vibration, the rates of which are as follows: Lowest Rubens, 10^{12} ; red, 4×10^{14} ; violet, $7\frac{1}{2} \times 10^{14}$; farthest ultra-violet, 10^{16} ; soft X-rays, 10^{17} , and hardest X-rays, 10^{18} . We see then that of this vast keyboard of radiant energy less than one octave produces visual sensations.

COLOR ABSORPTION

Now the question arises as to what is the source of chemical absorption of light. What is the mechanism? Here is where I will begin to get into trouble. It is evident in the first place that some elements are naturally colored. They are just born that way. Copper in its various compounds, except in a few of the cuprous, is generally colored, although you never can tell what color it is going to display. Many of the salts of the heavier metals are colored, and in those cases it is pretty easy to recognize that the element itself carries within it the color-absorbing mechanism. On the other hand, there are many cases, as you know, of elements which are not ordinary color producers, such as carbon, oxygen, hydrogen, nitrogen, and yet from these may be produced colored substances like nitrogen dioxide, where you have a highly colored substance produced from elements which do not normally give it. Then of course we have the great host of dyestuffs which likewise are made up of elements which do not

normally produce color compounds. It seems to me equally evident that in this case it is not in the atom but in the association of atoms of a particular type that we get the light-absorbing mechanism. Let me as a simple illustration show a few experiments of a primitive character. Here are three copper salts dissolved in alcohol. As you see, although possessing the same amount of copper, they not only have different intensity of absorption, but entirely different color. The cupric nitrate in alcohol has almost the same color which it has in water, rather faint. You will notice the typical blue color of copper salt. The cupric chloride in alcohol has a green color, but nevertheless when poured into the water gives once more the same cupric faint blue appearance. Here is cupric bromide, which you can hardly see through at all. It is a very dark brown in daylight, and yet it contains the same concentration of copper. The copper is always active in forming the color. If we should add to any one of the aqueous copper solutions a small amount of ammonium hydroxide you would get once more a very intense blue color. While we do not know the mechanism in this case, nor perhaps precisely in any other, yet we know pretty much what goes on in these solutions. When copper salts are dissolved in water we do not have the simple arrangement which we usually write as Cu cations and Cl, NO₃, etc., anions.

THE GROUP COLOR EFFECT

The work of numerous investigators has shown that in such cases as these we have unquestionably about the central positive ion a group of molecules or radicals which are held with much firmness in this co-ordination sphere which surrounds them. That cupric ion in water is really a cupric ion with four water molecules very firmly attached to it. They can, however, be driven out by ammonia, and ammonia does drive them out and produces cuprammonium, where we know much more definitely than we do in the other case that we have four molecules of ammonia attached to each one of copper. It is evident then, it seems to me, that in this case the copper atom contains within itself the absorbing mechanism, but that mechanism is affected more or less in its action by associated groups, thus changing the intensity and the frequency of the absorbed light, the light absorbed by its environment. Thus copper attached to four ammonia molecules does not produce just the same effect as copper attached to four water molecules, but it does a surprisingly similar thing. They both cut light out of the radiant energy system in the spectrum zone which we call visible light. Any two color substances are very closely akin. Whether they absorb in the violet or the yellow they are not far apart in their properties.

This problem of finding the source of the color-absorbing mechanism is not an easy one. In one case where I can show you a change of color due simply to a change of temperature we know exactly and quantitatively to what that change is due. In the mixture of two gases, NO₂ and N₂O₄, you will see as I heat this up that the upper part of the chamber becomes quite a good deal browner than the lower part. We can calculate quantitatively the relative amounts of N₂O₄ and NO₂. NO₂ is colored and N₂O₄ is colorless. NO₂ is formed at high temperatures, N₂O₄ at low temperatures.

A solution of cobaltous chloride in aqueous solution, with a small amount of acid added while hot, is very deep blue. If, however, it is cooled by being poured

into ice the color change is so absolute as to be the opposite of that which we had before; it goes from a bright blue to a bright red. The effect is partly due to the hydration by the ice, although the same experiment can be tried in other ways. This was the simplest way to show the experiment. But we see pretty clearly that there the phenomenon is due to a greater or less degree of hydration, probably a greater or less degree of driving out of the chloride ion from a complex by water. In the diluted aqueous solution this color of the cobaltic salt is characteristic. The hydration is diminished by increasing temperature, diminished by increasing concentration.

CHROMOPHORES

It is evident that the absorption of light in the visible spectrum is only part of a larger phenomenon which should be studied in its entirety if we are to obtain the fullest evidence as to the origin of color. Indeed, numerous investigations have shown that many substances which have no power of absorption in visible regions have pronounced absorption bands, as they are called, in the ultra-red, and especially in the ultra-violet. If then through some change in condition a colored substance changes to a colorless substance, as phenolphthalein does on the addition of an acid, it may be that the absorption band has simply ceased to exist, or it may be that the region of absorption has shifted slightly so as to bring it out of the range of the visible. If instead of being able to see less than one octave of the spectrum we could perceive several octaves of light as we do several octaves of sound, most substances would be colored, but those substances which absorbed in the neighborhood of the visible would be found to contain the same types of fundamental color groups or arrangements of atoms which occur in our dyestuffs and which Witt has called chromophores, groups which under a somewhat different environment, or attached to other chemical radicals, might cause visible color.

As in the case of indicators, it has been observed that most organic dyes are capable of existing in two or more forms in which the same atoms are in a different arrangement. Such arrangements, which pass over one to the other with such rapidity that it is rarely possible to isolate the separate substances corresponding to the different atomic arrangements, are known as tautomers, and numerous attempts have been made to show that the process of light absorption is due to the vibration of the atoms between two such arrangements in some sort of resonance with the vibration of light itself. These attempts, however, have failed, and indeed it will become evident that they were doomed to failure when we analyze now the exact nature of the process which must be responsible for the absorption of light.

ELECTRONIC VIBRATION

Let us for a moment forget the complicated facts regarding color absorption, of which I have been able to show only a few of the thousands which have been observed, and consider *a priori* what conditions must prevail in absorbing media. We may return once more to the analogous and more familiar phenomena of sound. If we hear a rattling sound in some piece of machinery we at once conclude that there is some loose part which is taking up a part of the energy of the machine and dissipating it by sound waves and by friction. Again, anyone who has played the piano has had the experience of finding some one note which appears harsh and unpleasant, and has discovered that

the fault is not in the piano itself, but in some piece of bric-a-brac in the same room which is set ajar by that one note and no other. This article, whatever it may be, has happened to be so placed as to determine a period of oscillation identical with one of the notes of the piano. It is said to be in resonance with that note, and the energy of sound of that particular pitch is absorbed by it. So a group of tuning forks of a certain frequency would absorb and act as a shield against sounds of that frequency, while notes of another pitch would pass through unchanged.

When we consider the factors that determine the natural frequency of vibration of such oscillator we find two that are of prime importance. The pitch of a violin string depends upon how tightly the string is keyed up; the tighter it is the higher the pitch or the frequency of vibration. But also the weight of the string is important. Thus while the E string is light and tense, the G string is not only left slack, but it is wound about with metallic wire to give it a greater mass. The greater the mass the lower the frequency of vibration.

These ideas are directly transferable from acoustical to optical phenomena, where, however, the resonators must now be electrically charged, and must possess an enormously high vibration frequency. In the molecules there are two sets of charged particles capable of acting as such oscillators. On the one hand the positively charged nuclei of the atoms, which have a mass approximately equal to that of the atom itself, and on the other hand the negatively charged electron with a mass more than a thousand times smaller. On account of the relatively high mass of the positive particles it seems probable that they never, or almost never, are capable of vibrating with a frequency sufficiently high to come within the scope of the visible spectrum, but rather cause absorption in the ultra-red. On the other hand, those light and indeed almost massless particles which we call electrons are usually held tightly enough so that their natural period is well above that of the visible spectrum, and they can therefore absorb light only in the ultra-violet region. Thus in the great majority of chemical compounds which are colorless the positive parts have too low a frequency and the negative parts too high a frequency to affect the visible spectrum. If, however, the constraints under which these electrons are held are in some way loosened their frequency of vibration will diminish, and ultimately they may become so loosely held as to absorb in the visible.

I once greatly perturbed one of our candidates for a doctor's degree who was coming up for his examina-

tion in organic chemistry by asking him why it was that when most organic substances were heated up they turned yellow. He didn't think that was a fair question. But it seems to me it is a rather interesting question. Why is it that when organic substances are heated up they turn yellow? Why don't they turn green or violet or indigo? If you will remember the spectrum with the red at one end, the violet at the other and beyond that the great range of the ultra-violet—supposing that you consider a substance in which the electrons are loosely held, but not quite loosely enough to get into the visible, it will be absorbing just in the ultra-violet region. Supposing that you make some minor change, perhaps a polarization of molecules, or some similar change in the organic molecules which will lower slightly the absorption period. Then that will

shift down into the visible. The first thing it strikes will be the violet. Taking out the violet leaves a preponderance of yellow, the complementary color which is found in general in the decomposition of all organic substances.

Let us then examine more intimately into the structure of the molecule in order to ascertain, if we may, what relation it bears to the tightness of the constraints which we may conceive to be operating upon the individual electrons. The wonderful development of organic chemistry, which is the chemistry of the carbon compounds, has been due in great measure to the introduction of the so-called structural formula.

The theory of the combination of atoms and the structure of the atom, which I published a few years ago, can hardly be used to predict the phenomena of color, as it was to a large extent derived from the phenomena of color. The

color absorption was one of half a dozen of the leading methods by which we were able to attack the problem of the internal structure of the molecule and the atom. I might mention one more experiment. The substance NO_2 is colored brown, although when it polymerizes to N_2O_4 it is not colored.

There is an organic substance which I want to speak about which is similar, being water white, though a little opaque due to turbulence. It is a solution of triphenyl methyl chloride in benzene. Most of you are familiar with the method by which Gomberg succeeded in obtaining a free radical from this solution by simply adding zinc dust. The zinc combines with the chlorine, leaving the radical triphenyl methyl free, which forms about the zinc in a brown film. That color is not particularly striking, but it is a very peculiar colored substance, belonging to the same class as NO_2 , and I shall have occasion in a moment to speak of both of them

GILBERT NEWTON LEWIS

again. Just to run very hastily over the points involved here, it seemed to me, from the facts of the periodic table alone, that there was a very strong tendency on the part of atoms and molecules to conform to certain very simple types, and to a very small number of types. By a study of the periodic table several investigators were led independently to the idea of a structure of certain atoms, much as I have stated here.

ARRANGEMENT OF NUCLEUS AND ELECTRONS IN THE ATOM

The first one represents by its cross the nucleus of a helium atom, and by the two points, the two electrons which just balance the charge (Fig. 1).

The next one is the neon atom, where we have once

FIG. 1. HELIUM, NEON AND ARGON

more the two electrons in the center, but outside of that this group of eight which Langmuir has called the octet, this group of eight electrons which surround the central group. In the old days I used to speak of this as the cubic theory of the atom, but when my paper appeared I had already rather changed from the idea of cubic to the idea of tetrahedral. The figures are usually made in three dimensions, but let us imagine each of these atoms has a center with four pairs of electrons fairly close together, surrounding in tetrahedral form this central portion, and here in the case of argon with an atom number of 18 and therefore requiring 18 atoms to make a neutral atom, we have one

FIG. 2. HYDROFLUORIC ACID AND NEON

of these tetrahedrons composed of four of these electron pairs, and then outside of that another.

These rare gases are not the only ones. These are very simple configurations. Indeed, if I should put on the screen the fluoride ion or the oxide ion they would look exactly like that middle ion picture, and if I put the chloride ion on the screen it would look exactly like the argon picture (Fig. 1). If I put potassium on the screen it would look just like the argon picture. There are certain few types to which these elements belong. They may form these types by forming ions—that is, by lending or gaining enough electrons to form somewhat rudimentary types—and they may form these by another manner, and this, to the chemist, is the essential feature of that theory which I was fortunate enough to work out just before the war: the new theory of the chemical bond.

THE ELECTRON BOND

An electron passing from one atom to another and thus in some way bringing about a chemical reaction

goes way back to the Faraday lecture of Helmholtz. But that represents only a small part of what we may call the function of the electron in chemical change. Fluorine, which is represented by the neutral atom, would have one fewer electron and therefore does not represent the group of eight, can take on that additional electron to make this very considerable configuration which we have here, not by taking that electron away from another atom but by bringing the atom along too. And by that cross over on the left (Fig. 2) I have represented the nucleus of the hydrogen atom, which instead of parting with its electron goes along and together with the fluorine produces this neutral group of eight electrons in the outer shell. So you see by taking on hydrogen you get once more this formation which is characteristic of so many compounds and which is represented by neon. In other words, that pair of electrons held between two atomic centers is the very thing which we have been looking for under the name of the chemical bond.

There is no question that organic chemists have always had a feeling within themselves that this bond between carbon and hydrogen was not a mere product of the imagination but was a real entity, was a real physical thing, and here I believe we may state just what that bond is. It is that pair of electrons which joins two atoms. Here, for example, we have almost precisely the same configurations. Only carbon has to

FIG. 3. METHANE AND WATER

take on four hydrogens, having four less electrons itself, and oxygen has to take on two hydrogens to make water, which has the same configuration (Fig. 3).

THE BONDS IN THE HALOGEN GROUP

Then in addition to the bond between these atoms and hydrogen—hydrogen is a very unusual type of atom—we can see how two of these groups holding one pair in common are able to satisfy their complete groups of eight. It is these two figures, and one or two following, which I want to call attention to particularly, because there it seems to me that we have one of the few cases where we know almost precisely what the absorbing mechanism is in colored substances.

You see these figures all look much alike. No matter what formula they are attached to, there are only a few types altogether. This large group in Fig. 4 is fluorine, F_2 . Fig. 5 shows methyl fluoride. The only difference is that it has three hydrogen atoms and different nuclei, of course. The bond, that pair of electrons which is holding together the repellent positive particles, may be a tight bond or it may be a loose bond. It is a tight bond in both of these gases.

Chlorine has a similar structure to the fluorine molecule, except that it has in addition an exterior shell over that which we see in the fluorine molecule. As these two atoms get heavier and heavier the pull on

that central bond becomes greater, and in bromine it is greater than it is in chlorine, and in iodine it is greater than it is in bromine, and we know that iodine vapor at quite a moderate temperature decomposes into two atoms of iodine. Unlike the case where we have a decomposition substance produced, the break is right here between these two electrons, one going to the

FIG. 4. FLUORINE

one and one to the other; we get that peculiar case of which only a handful of instances are known, of the hundreds of thousands of chemical substances, where you have a molecule with an odd number of electrons, and whenever you get a molecule with an odd number of electrons you get color. There is only one known case, that is NO, of one of these substances with an odd number of electrons that are called the odd molecules which do not absorb light. In other words, they are substances one of whose electrons at least is held by so loose a constraint as to absorb light in the visible region. It is the bond electron that is active. I don't know whether it stays in the location shown or not, when the molecule breaks apart, because these molecules are peculiar things; but no matter where it goes, you have always an odd number. And that electron is held by much weaker constraints than all others. You remember when the two odd molecules came together by a bond forming N_2O_4 , the thing became colorless. That is not the case with iodine atoms, and in fact we must now pass to the case of the odd molecules themselves.

This, by the way, is the type of all the organic molecules of which none were known a few years ago and which since Gomber's discovery have been increased by dozens, both for carbon and hydrogen compounds. It is not necessary always for this bond to break before these electrons begin to be loosely held; and so iodine

FIG. 5. METHYL FLUORIDE

which is almost broken shows a gray color in the vapor phase of I_2 . Bromine shows less. Chlorine shows less. Fluorine, as you know, is almost colorless; and there, by every evidence we have, that bond is a tight one. Think, in spite of its tremendous affinity, how relatively inert a substance like chlorine is, compared to a substance like iodine.

ORGANIC BONDS

The typical bond of organic chemistry is shown in Fig. 3 with methane—a tight bond in which the electrons are held with such firmness that they don't absorb light in the visible and they don't absorb light in the ultra-violet, as far as it is possible to investigate that substance.

Ethylene, Fig. 7, is a typical unsaturated organic substance, in which the bond pair of electrons are in the position which is one of greatest stability—the pair of electrons held exactly between two central positive atoms. It is impossible for the double bond, where you have two electron pairs taking part simultaneously, to be in the middle of a line exactly joining these centers. They are crowded apart, and not only our evidence from color but our evidence from chemical reaction and the great variety of other evidence we have shows that the electrons in double bond are held much more loosely. And you will find that of all the color compounds of

FIG. 6. CHLORINE

organic chemistry except these rare ones which have the odd electron every one contains a double bond, and most of them are composed very largely of radicals with double bonds. That double bond is not ordinarily

FIG. 7. ETHYLENE

sufficient. The electrons, although much less firmly held than in the single bond, are not ordinarily loosely enough held to produce absorption of visible light. Their vibration frequency is in the ultra-violet, but by adding to the unsaturation of these molecules, by doing the various things which the organic chemist will tell you will loosen that bond, even if he hasn't any interest in the problem of color at all, you will find that these enter into the domain of the dyes.

QUANTUM THEORY WILL NOT ALTER PRESENT COLOR THEORY

I do not wish to make this problem of color seem more simple than it really is. It will be long before we reach any complete understanding of the thousands of detailed observations which have been made in this field, and we do not know as yet how far our ideas will have to be modified by that great wave of bolshevism in physics which is known as quantum theory. Einstein, perhaps the profoundest thinker in physical science that this century has known or will know, and whose name has recently become almost a household word through the offices of the daily and the comic press, was one of the first exponents of quantum theory. But, as he once said to me in conversation, "Quantum theory is not yet a theory in itself, it is simply a negation of the older theories." It seems, however, that in the region of loosely bound electrons which characterize our colored substances the further development of the quantum theory will not greatly modify such conclusions as we have discussed today.

A Study of the Saturated and Unsaturated Oils From Shale

An Investigation of the Amount and Causes of Unsaturates in Shale Oils—Cracking During Retorting and Distillation Accompanied by an Increase in Saturation—Unsaturates Vary With Nature of Shale and Methods of Pyrolysis

By C. W. BOTKIN

Research Chemist for the American Shale & Petroleum Co.

WHEN distillates from our shale oils are treated with an excess of sulphuric acid, there is a large loss of oil. This indicates a high percentage of unsaturated compounds and considerable refining loss if the oil is to be refined by the usual acid treatment. Both the refining methods and the utilization of shale oil depend to a large extent on the quantity and nature of the saturated and unsaturated constituents. Hence it is highly desirable to know the percentage and distribution of saturates and unsaturates, the factors which tend to increase the former and diminish the latter, and any physical or chemical properties of the unsaturated compounds which may aid in indicating proper methods of retorting and refining or in suggesting uses for the oil. Most of the experimental work of this paper was done to obtain information for practical purposes and while no attempt has been made to study a large number of oils or to make an exhaustive study of shale oil hydrocarbons, it is hoped that some valuable information has been obtained concerning the extent of their saturation, the cause of the unsaturates, the distribution of the saturates, the effect of cracking on saturation, and some of the properties of the unsaturated substances.

THE DETERMINATION OF SATURATES AND UNSATURATES

In all determinations the oil has been treated with two volumes of sulphuric acid (c.p., dens. 1.84) and the volume of the oil remaining expressed in percentage of the original volume is the percentage of saturated compounds. The difference between this and 100 is the percentage of unsaturated compounds. Some chemists may question the propriety of the term "unsaturated" to designate these substances and also the use of sulphuric acid as a means of measuring the amount of unsaturated compounds, since in addition to combining with unsaturated bodies, water and other substances are dissolved by the acid, basic constituents are neutralized, polymerization may occur and some aromatic compounds may be absorbed.¹ However, this method is apparently satisfactory for practical purposes when used on shale oils and is considered sufficient for the experimental work of this paper. The method² used is as follows: Five or 10 c.c. of the oil is measured into a 9- or 18-g. 50 per cent Babcock cream-test bottle and a double volume of the acid added. The bottle is kept cool by immersion in cold water but is shaken gently at intervals until finally with vigorous shaking there is no longer a rise in temperature. Then the bottle is filled to the neck with acid and centrifuged at 1,000 r.p.m. for three minutes. The oil remaining is now

brought into the graduated neck of the bottle by addition of more acid and the centrifuging is repeated. The percentage of saturates is calculated from the volumes of the remaining oil and the original oil. When the acid concentration is constant, the results check within 0.5 per cent. A correction is made whenever the water content of the oil exceeds this value. When the oil is solid, it is warmed enough to keep it in the liquid condition.

RESULTS OF DETERMINATIONS

Using this method, saturation tests have been made on shale oils from Colorado, Wyoming, Utah, Nevada, Quebec, England and Scotland. The oils tested include crude oils produced by twelve different plant processes of retorting and crude oils obtained from eleven different shales in laboratory retorts. Most of the plants were in an experimental stage. The laboratory retort was of the usual iron, "mercury-distillation" type op-

erating without steam. The results obtained by these determinations are given in Table I. The saturates in the oils tested very between 12 and 41 per cent. This indicates a high percentage of unsaturated compounds in the crude oils from all of the above sources and methods of retorting.

CAUSES OF THE HIGH PERCENTAGES OF UNSATURATES

—LOW CONTENT OF HYDROGEN

One explanation of this high percentage of unsaturates in shale oils is that the kerogen or oil-yielding material of the shale does not contain sufficient hydrogen to produce saturated compounds with a large portion of the carbon in the hydrocarbons volatilizing during the destructive distillation of the shale. This is indicated by the fact that free carbon is present in all spent shales and by the results of chemical analyses of the kerogen or shale. Analyses of the kerogen from Scottish shales reported by Mills³ show a hydrogen to carbon ratio of about 1 to 6.9. Robertson states⁴

¹Technical Paper 181, U. S. Bureau of Mines, p. 11.

²Modified from Egloff, Gustav, and Twomey, MET. & CHEM. ENGR., March, 1916, p. 247, and Technical Paper 181, U. S. Bureau of Mines, p. 11.

³J. Inst. Pet. Tech., 1916, p. 238.

⁴Proc. Roy. Soc. Edinburgh, vol. 34 (1914), p. 190.

that for Broxburn shale this ratio varies between 1 to 6 and 1 to 8 and over, and that the greater the proportion of hydrogen the larger the yield of oil. An average of six ultimate analyses made on Nevada, Utah and Colorado shales by J. D. Davis of the United States Bureau of Mines⁵ gives a ratio of 1 to 7.8. The ratio of hydrogen to carbon is about 1 to 5.6 for the average gravity paraffine hydrocarbon found in mineral oils and is 1 to 6 for an olefine. We would not expect an organic substance such as kerogen, which apparently contains no free carbon and which has a hydrogen to carbon content of 1 to 7, to decompose with the formation of a large percentage of paraffines in which this ratio must be 1 to 5.6 unless considerable free carbon is formed. It is probable that the higher the hydrogen content of the shale the greater will be the percentage of saturates in the oil, and it is evident that cracking would tend to increase the saturation of the oil if the hydrogen content of the permanent gas and coke is much less than one-seventh of the carbon content. In other words, it is possible that the smaller the yield of oil from a given shale which is completely carbonized the higher may be the percentage of saturates in the oil. While the above data are not sufficient for far-reaching conclusions, they indicate that there is not enough hydrogen in the organic material found in shales to produce saturated compounds with all of the carbon, and consequently for a maximum yield of oil it must be highly unsaturated.

CRACKING OF THE OIL

Some of the inventors of shale retorts in this country have suggested another explanation for the high percentage of unsaturates. It is generally known that the overheating of petroleum oils causes a decomposition or cracking of the oil and that this cracking at atmospheric pressure is accompanied by an increase in the percentage of unsaturated compounds. Using this as a premise, they conclude that the high temperature used in the destructive distillation of the shale cracks the oil and produces the unsaturates. Acting on this principle, retorting processes have been planned to operate at a minimum temperature, thereby preventing cracking and thus producing a more saturated crude oil. Some advocate steam-retorting as a preventive of cracking and claim to obtain a more highly saturated product in this way.⁶ Redwood states⁷ that in Scottish practice retorting with steam prevents the formation of olefines. Others claim that the beneficial effects of low-temperature carbonization of coal on the distillates applies also to shale. However, the writer has not been able to find any published data to prove that the cracking of shale oil tends to increase the unsaturates or that more saturates are obtained when the retorting is done at low temperatures or with steam. In November, 1919, G. W. Wallace⁸ reported that he had found that shale oils crack more readily than petroleum oils and that a large amount cracking occurred during distillations at atmospheric pressure. In January of last year the writer began a study of the extent of this cracking and found that the oils tested cracked to an unusual degree when distilled at atmospheric pressure and were also unusual in that the oil after distillation contained a much larger amount of saturated

compounds than the original crude oil.⁹ This unexpected increase in saturation, produced apparently by cracking of the oil, indicated that the high percentage of unsaturates might in part be due to low-temperature carbonization, which, while serving as a preventive of decomposition as intended, acted also at cross-purposes and produced an oil lower in saturates.

EXPERIMENTS IN SHALE RETORTING

The influence of low- and high-temperature retorting on saturation and the effect of the presence of steam and hydrogen gas during retorting were studied by distilling samples of a Colorado shale in a laboratory retort under four different conditions. In the first two distillations the oil was removed at as low a temperature as possible without steam; in the third and fourth distillations the oil was removed at as low a temperature as possible introducing steam at the base of the retort; in the fifth and sixth distillations the oil was removed at a low temperature introducing hydrogen instead of steam; and in the seventh and eighth distillations the oil was removed by a more rapid application of heat but its rapid escape prevented by an iron, air-cooled, reflux condenser, which returned the heavier oil to the hot shale in the retort. The temperature of the shale was obtained by a 900 deg. F. Tagliabue thermometer inserted in a thermometer-well which reached to a point near the center of the shale. The vapors coming from the retort were passed through a water-cooled vertical condenser and the oil and water condensing were received in a graduated cylinder or a cylindrical trap. The permanent gases were conducted from the receiver through 5 per cent sulphuric acid in a Meyer tube and measured by a wet-test gas meter. At the end of the distillation boiling water was passed through the outer tube of the condenser to melt and remove any oil which had solidified in the inner tube. The oil in the receiver was then measured and after

washing with water was kept at 100 to 130 deg. F. in tightly stoppered bottles for three days in order to secure a rather complete separation of water. At the end of this time the volume of the oil was remeasured and samples taken for the saturation tests. The portions of oil obtained under each condition were combined and a fractional distillation made on each. These fractionations were made on 50-c.c. portions in a standard 100-c.c. Engler distilling flask. The coke values were obtained by weighing the flask before and after the distillations. The oil percentage by weight was calculated from the gravity and volume of the oil. The weight-percentage of gas was obtained by difference and its volume was measured by meter. A second distillation of the once-distilled oil was made to 410 deg. F. to determine the increase in this fraction caused by cracking. The results of the retorting experiments are given in Table II and of the fractionations in Table III.

RESULTS OF SHALE-RETORTING EXPERIMENTS

The most important result shown by the data in Table II is that no one of the four conditions of retorting produced from this shale a crude oil containing over 30 per cent of saturates. This is doubtlessly due to the low hydrogen content of the shale and indicates that the nature of the shale and not the process of retorting is by far the predominating factor in determining the percentage of unsaturates. Where the cracking is minimized by the steam-retorting the unsaturates are about 15 per cent higher than in the retorting with the reflux condenser, where the decomposition is at a maximum. The presence of free hydrogen in the retort does not affect the saturation of the oil, except as it acts similarly to the steam in preventing some of the cracking through speeding up the removal of the oil vapors.

The position of the thermometer and the manner of application of heat to the retort were such that the readings taken when the oil was about half off more nearly indicate the decomposition temperatures of the shale than the other readings. These temperatures are between 740 and 755 deg. F. and are independent of the presence of steam or hydrogen. This temperature is probably somewhat of a constant for a particular shale and like the hydrogen content of the shale is not dependent on the process of retorting. The maximum boiling point of the shale oils (705 deg. F.) is probably lower than the average decomposition temperature of the shale, consequently the longer the oil vapors are subject to the higher temperatures in the retort the greater the tendency to decompose the unstable portions

of the oil. The introduction of steam or hydrogen increases the rate of flow of the vapors, thus diminishing the decomposition, and under these conditions there is a somewhat larger yield of oil of higher specific gravity and lower content of saturates. The cracking of the shale oil vapors is apparently a decomposition of unstable unsaturates with the formation of coke, gas and a rather high percentage of saturated lighter oils. Hence if we would increase the saturates in the crude oils by retorting conditions, we must not limit the decomposition to the shale alone but subject the oil vapors to the higher temperatures long enough to secure a decomposition of the unstable, unsaturated compounds.

Table III shows the results of a fractional distillation of the oils obtained under the four different conditions of retorting. The oil obtained with steam, containing 16.6 per cent of saturates, cracked to the greatest extent on distillation, yielding 10 per cent of coke, 2.95 per cent of gas and 86.6 per cent of oil containing 35 per cent of saturates. Where the increase in saturation is less, there is a corresponding decrease in the coke, gas and cracked-gasoline values and there is a less decrease in gravity, all of which would be associated with a smaller amount of decomposition. The once-run oil in all four cases is much the same in gravity and saturation, excepting that the oil retorted by a maximum of cracking (Nos. 7 and 8) is lighter due to a higher content of gasoline and kerosene and has a correspondingly less proportion of heavy oil. The decomposition, which was not completed in the retort, is apparently complete when the crude oil is distilled at atmospheric pressure without steam or other preventives of cracking.

EFFECT OF DISTILLATION OF THE OIL ON SATURATES AND UNSATURATES AND THEIR DISTRIBUTION

A study was made of the effect of distillations at

atmospheric pressure on the cracking of shale oils and on the amount and distribution of the saturates and unsaturates. The results obtained with three different types of oils will be given somewhat in detail. These oils include an asphaltic oil from a Utah shale, an oil rich in paraffine from a Nevada shale and an oil of mixed-base variety from a Colorado shale. The samples for distillation were taken from 5-gal. cans which were originally filled from batches of oil obtained in quantity from shales representative of those being worked at three different places in the states mentioned. An 800-c.c. portion of each of the oils was distilled at atmospheric pressure (24.2 in. in Golden, Col.) from a 1,000-c.c. pyrex distilling flask. The vapors were condensed in a vertical water-cooled condenser ending in a trap from which any permanent gas formed by cracking was conducted through a wet-test gas meter and measured. The oil from the trap was removed at such intervals as to obtain 10 per cent fractions, and when each fraction was complete a reading was taken of the still temperature, vapor temperature and the amount of gas formed. The gravity of each cut was determined by hydrometer and after removing a sample for a saturation test the remainder was composited and is designated as once-run oil.

After determining the gravity and saturation of the once-run oil a portion (580 or 600 c.c.)¹⁰ was distilled a second time from a similar flask and the same kinds of data taken as in the first distillation. The twice-run oil thus obtained was then composited as before and a third distillation made (except with the mixed-base oil)

¹⁰With the mixed-base oil the gasoline to 410 deg. F. was excluded and the second distillation made with 500 c.c. from a composite of the remaining oil.

in the same manner, recording similar kinds of data. The percentages of coke were determined by weighing the empty flask before the distillation and the flask with contents after the distillation. The temperatures were taken with Tagliabue thermometers. For the vapor temperatures the bulb of the thermometer was in the usual position and for the still temperatures it was placed in the center of the flask about 2 to 3 mm. from the bottom. The data obtained with the asphaltic oil are given in Table IV, with the paraffine base oil in Table V, and with the mixed-base oil in Table VI.

RESULTS OF DISTILLATIONS OF SHALE OILS

A study of Tables IV, V and VI will justify the following statements relative to the cracking and the the saturated and unsaturated content of the oil:

(1) There is a large amount of decomposition during the distillation of the crude oil. Measured in percentage of permanent gas and coke formed, it is 4.9 for the paraffine-base oil, 10.2 for the mixed-base oil and 18.9 for the asphaltic oil. It is also manifest by the lowering of the vapor temperature and by a decrease in the specific gravity of the fractions.

(2) The cracking occurs after the still temperatures have reached 600 deg. F. (vapor temperatures 500 deg. F.) and is most rapid when the still temperature is about 800 deg. F.

(3) Compared with the first distillation, the decomposition during the second and third distillations is very slight, occurring only at the higher still temperatures when the distilling flask is nearly dry and probably at a temperature exceeding that indicated by the thermometer. This shows a high stability for the heavy fractions of the once-run oils and indicates that after the first distillation shale oils do not crack more readily than petroleum oils.

(4) The decomposition of the crude oils is accompanied by a considerable increase in the saturation of the oil. This is shown by an increased saturation in the heavier fractions and by a higher saturation value for the once-run oils. The volume of the saturates increased 29.0 per cent for the asphaltic oil, 38.8 per

cent for the paraffine-base oil, and 73.6 for the mixed-base oil. (Additional values for this increase may be found in Table III.)

(5) The second and third distillations have little effect on the percentage of saturates and unsaturates, but they show clearly the distribution of these constituents. The lighter fractions have the highest saturation (50 to 60 per cent) and the saturates decrease with the increase in gravity and boiling point and reach a minimum (18 to 40 per cent) in the heaviest fraction.

(6) The decomposition is apparently one of heavy unsaturated compounds which are unstable at the still temperatures necessary for distillation at atmospheric pressure without the introduction of steam or other gases, and is accompanied by the formation of permanent gas, coke and lighter oils containing a high percentage of saturates.

While it is quite obvious that the compounds undergoing decomposition are heavy and unstable, more experimental evidence is desirable in support of the statement that the substances decomposing are unsaturates. A subsequent paper will present the results of study along this line, the determination of some of the properties of the heavy constituents of shale oils, and a discussion of the results obtained in the different portions of the investigation.

Colorado School of Mines,
Golden, Col.

Section of Sugar Chemistry and Technology, A.C.S.

AT THE Rochester meeting of the American Chemical Society, thirty-three papers were presented before the Section of Sugar Chemistry and Technology, as compared with the very few read at the St. Louis meeting and seventeen at the Chicago meeting last September. Approximately 150 enrolled as members of the section. The members voted to request that the section be made a division; that present officers be re-elected until the creation of the division; that the executive committee be authorized to pass judgment on all papers for the next meeting, assigning a time limit for reading and accepting or refusing papers, as seems best.

In addition to a number of papers presented which described improved methods of analysis and laboratory equipment designed to make possible more accurate factory control work, the following papers were concerned more especially with the technology of cane and beet sugar manufacture.

A Comparison of the Results in the Process of Desugarization With the Steffen Lime-Process, the Barium Process and the Strontium Process, by M. Potvliet. Experimental work indicated by the title was described. Processes were compared on the basis of purity of resulting liquors 81.4 per cent for the lime, 93.79 per cent for the barium and 90.90 per cent for the strontium process. Fewer operations were said to be necessary to extract the sucrose from molasses by the barium and strontium processes. Of the sugar originally present in the molasses there was obtained as granulated sugar by the lime process 35.45 per cent, by the barium process 43.94 per cent and by the strontium process 43.18 per cent. It was claimed that not the slightest trace of barium is present in the final sugar and that more raffinose is found to be eliminated by the barium process. In the discussion which followed the presentation of this paper, the statement regarding the entire absence of barium was questioned.

The Effect of Varying Hydrogen Ion Concentration Upon the Decolorization of Cane Juice With Carbon, by J. F. Brewster and W. G. Raines. *The Effect of Some Decolorizing Carbons on the Color and Colloids of Cane Juice*, by J. F. Brewster and W. G. Raines. These two papers reported the results of experimental work with four different carbons. Emphasis was laid on the fact that decolorization depends greatly on the hydrogen ion concentration, but that it is not best to use too high hydrogen ion concentration on account of inversion. It was found that simply acidifying also produced decolorization; this point was considered in the conclusions. It was found also that by adding the carbon, heating, and acidifying with H_3PO_4 to the desired hydrogen ion concentration, and also adding enough lime before filtration sufficiently to reduce acidity, equally good decolorization was obtained and the $Ca_3(PO_4)_2$ was removed at the same time. Inversion was tested by boiling the juice at various hydrogen ion concentrations. Both color and colloids removed were determined after the use of different carbons, and these results were compared with color and colloids removed by the sulphur-lime process. Regulation of the hydrogen ion concentration is a much better method for controlling acidity than the usual method of titration.

A Study of Beet Gum—I. Separation From Final Molasses, by H. S. Paine and C. F. Walton, Jr. A considerable amount of gum was prepared from final molasses by dialysis, and various preliminary tests made of its composition and properties. A minimum specific rotation of about -29 deg., changing after hydrolysis to about $+58$ deg., was indicated. The gum was precipitated by an alcohol-acid mixture. The material yielded 32 per cent furfural phloroglucide. A positive test for galactan by the mucic acid method was not obtained. The gum increased the viscosity of sugar solutions and incidentally color, to a much greater extent than would be expected from its actual weight. Crystallization experiments indicated that the gum exerts a marked effect in diminishing the rate of crystallization of sucrose.

Colloids in Beet Sugar House Liquors and Products, by H. S. Paine, C. G. Church and F. W. Reynolds. The primary object was to determine the amount and character of the colloidal material present at successive stages in the factory, to ascertain the importance of the rôle played by colloids in sugar-house difficulties, and to attempt the solution of such difficulties. Colloids were determined by dialysis. Organic rather than inorganic colloids apparently play the predominant part in factory troubles of colloidal character; the organic colloidal material not eliminated by clarification consists to a considerable extent of one or more gums. Gum was found in relatively considerable amount in washed cold saccharate cake. A substance resembling pectin in its reactions was found in diffusion juice, but not in the subsequent products. Under usual factory conditions the amount of colloids present is apparently primarily dependent upon the character of the beets worked.

Sugar Filtration in Factories and Refineries, by H. J. Runyon, Jr. This was a very interesting paper from the engineering point of view both to sugar-houses and refineries but applies principally to refining practices. The author stated that lime and phosphoric acid defecation has become unsatisfactory in refineries with the advent of pressure filtration, because the precipitate is too gelatinous; it has been largely displaced by kieselsguhr and the use of filters of the Sweetland type.

Breadth and Scope of Chemical Patent Claims*

Review of Decisions Holding Patent Claims Void for Undue Breadth and of Others Holding Them Valid for Merited Scope—Citations From Cases Bearing on Chemical Equivalents and Essential Differences

BY C. H. BIESTERFELD

INVENTORS working along chemical lines are frequently confronted with the question of properly drafting comprehensive claims to cover a number of substances which they have successfully employed in new processes or compositions. In many cases such substances belong to the same chemical family and in some cases they do not. In some cases they constitute distinct species and in some cases only equivalents. The courts have clearly decided questions relating to the scope and construction of chemical claims which cover a group of substances, and the following is a digest of most of the cases.

CASES HOLDING CLAIMS VOID FOR UNDUE BREADTH

Incandescent lamp patent, 73 O. G., 1,289. The claims covered "carbonized fibrous or textile material," although the patentee had made filaments out of carbonized paper only, and had not discovered any other species of carbonized fibrous or textile material. It was proved that bamboo was particularly valuable as a filament and the court held that the claims were void for undue breadth, saying that there was no generic quality in all such materials which adapted them to the purpose.

Matheson vs. Campbell, 78 Fed., 910. The patentee tried to cover "any sulpho acids of any radical," which included 100 or more substances, and he described only a few. The evidence showed that most of the group of 100 were inoperative. Held that he could not speculate on the equivalents of his invention and he was not entitled to a monopoly of all substances which might be found by future experiments to be equivalents of his three or four disclosed substances.

Rickard vs. DuBon, 97 Fed., 96. The claim recited "applying an alkali to the leaves," but the specification named only KOH and the evidence in the trial showed that NaOH was inoperative when applied to leaves. The court held the claim void as being too broad.

Bracewell vs. Passaic Print Works, 107 Fed., 467. The claim covered all zinc compounds, although the specification described only zinc oxide, hydrate and carbonate. The evidence showed that zinc sulphide and chloride would fail and that the chemists were agreed that untried zinc compounds could not be used with certainty. Patentee tried to have the specification read into the claim, but the court refused, since his specification said "any zinc compound may be employed." The court held the claim void, saying: "He stretched his net to catch as infringers all users of zinc compounds, and if he has stretched it to the breaking point, he has only himself to blame. The courts should be liberal in construing patents, but they cannot rewrite the description and claims; they cannot construct an entirely

new patent even to save a meritorious invention. If the complainant's contention be correct, a patentee can claim blindly an entire group of compounds, relying on the court after subsequent investigation and experiment to limit the claim to the one which gives the best results. This will not do."

Lumber Anti-Stain vs. Nester, 178 Fed., 927. Claim 1 recited "applying to wood a weak alkaline solution," and the specification described NaHCO_3 . Claim 1 was met in terms by lime water applied to wood, and the court refused to limit the claim to NaHCO_3 because the patentee had nowhere shown any intention to so limit it. Claim 1 was held void. Claim 2 covering only NaHCO_3 was also held void because the patentee had regarded lime water and NaHCO_3 as equivalents.

Empire Circuit Co. vs. Channon, 168 Fed., 705. The claim said "non-combustible and non-conducting material," the specification describing a fire curtain made of asbestos or the like on one side, and metal on the other. The prior art showed a curtain of firebrick on one side and the court held the claim anticipated, refusing to narrow it because the patentee had nowhere indicated his intention to place a limited meaning upon the broad terms used.

Dosselman vs. Neymann, 167 O. G., 983. Patent Office decision. The claims recited "ketonic finish softening material," but only acetone was described in the specification and it did not appear that all ketones would operate for the purpose described. The claim was rejected.

Ex parte Steinmetz, 224 O. G., 363. The claim recited "titanium compounds," but the specification described only TiC and TiO_2 as being fit for electrodes. Commissioner Ewing held the claims too broad.

Excelsior Drum vs. Scheip & Vandergrift, 173 Fed., 312. The claim recited "a reinforcing band," but the specification described only a spirally wound band surrounding a horn between its ends. The claim was held void as being too broad on the ground that a broad claim cannot be based on a description that is limited to a single device and does not present it as an example of a preferred structure. This case shows that the doctrine has been applied to mechanical cases also.

CASES HOLDING SUCH BROAD CLAIMS VALID

American Sulphite vs. Howland Falls, 60 Fed., 395. The claim recited "a continuous lining of cement," and the specification stated that the lining might be of any material which is acid resisting and capable of being made plastic and adhesive. . . . A convenient material is portland cement . . . cement mixtures, sand and portland cement, sand and tar, etc." Held that the claim covered all cements having the properties set forth and that equivalents must be such as skilled chem-

*Journal of the Patent Office Society, vol. 2, No. 12, pp. 598-608, August, 1920.

ists might be expected to find as answering the requirements of the described conditions.

Fullerton vs. Anderson, 166 Fed., 443. The claim called for bleaching nuts by a "weak acid," while the specification stated that acetic acid, among other acids, was suitable for liberating chlorine for bleaching. Sulphuric acid was not described, but the court held that it came within the term "weak acid" and that the patentee was not obliged to experiment with all weak acids and that any acid which would liberate chlorine would be covered. The court intimated that some weak acids might be inoperative but that the commoner ones would be operative, and therefore the broad claim was valid. In this case any chemist could readily mention the weak acids which would liberate chlorine for bleaching purposes.

Welsbach vs. Sunlight, 87 Fed., 221. The claims covered "paraffine or other suitable material," and the specification said that any substance setting hard at ordinary temperatures and burning without mechanical destruction of the mantle would suffice. It was proved that collodion was known to have these properties at the date of the patent and it was therefore held an equivalent. The claims covered, under the construction given them by the court, all substances which were known by chemists to answer the requirements of the specifications.

Malignani vs. Hill-Wright Electric Co., 177 Fed., 430. The claims covered all substances which would "gasify by heat and combine with gases generated by the filament," while the specification mentioned arsenic, sulphur and iodine for the purpose of removing the oxygen. This claim was held valid, the court saying that the patentee was not required to specify all known substances which might be used and that the claim covered all such known substances, including phosphorus. This case held as valid a comprehensive claim which was functionally stated.

There is a unanimity of opinion in all these cases. They hold that in order to sustain a broad claim covering a whole class or group of substances, it must appear either (1) that the inventor has shown with reasonable certainty in the specification that all the members of the group claimed are operative, or (2) that it would be obvious to the average chemist that all the members of the group are operative. If upon trial the evidence shows some members to be anticipated or inoperative, the claim is held void unless the patentee in his specification indicated that he confined himself to his described substances and their equivalents.

HOW CAN INVENTOR CLAIM PROTECTION?

The question arises, How may the inventor obtain protection for those members of the class which his specification enumerates? Is it necessary for him to try them all out before filing a broad claim? Will it suffice for him to claim only one preferred substance and state in the specification that the others are equivalents, thereby hoping to gain the protection of the doctrine of equivalents? In *re Ellis*, 167 O. G., 981, is apparently the only decision which attempts to solve this difficulty. *Ellis* had claimed all "cyclic CH₂ hydrocarbons" as ingredients of finish solvents, and his specification had named about twenty such hydrocarbons. The term "cyclic CH₂ hydrocarbons" was apparently the only generic expression which could include the substances named. The Court of Appeals

held the claim valid in a well-considered decision in which the following points were brought out:

(1) It is unnecessary to investigate experimentally all members of the class, but only necessary to enumerate a fairly representative number to make it appear that the whole class is operative.

(2) There must be a claim in the case sufficiently broad to cover the whole class and such claim must define the essential quality of the class which renders it operative for the purpose described.

(3) Should any members of the class be found later to be inoperative, the court will restrict the claim to cover only the members described and their equivalents.

In regard to the first point, all that is necessary is to describe a fairly representative number, say from ten to twenty of the members of the class, to establish a *prima facie* case of operativeness for the whole class.

CLAIM MUST BE COMPREHENSIVE

In regard to the second point, there must be a comprehensive claim, and it will not suffice to claim only one member. The only authority cited by the Court of Appeals is *Read Holliday vs. Shulze-Berge*, 78 Fed., 493, but this case was only dictum and it confused the distinction between species and equivalents. An equivalent is a thing which performs the same function, and performs that function in substantially the same manner as a thing of which it is alleged to be an equivalent. (Walker, par. 354.) An equivalent for one ingredient of a patented composition of matter is anything which in that composition performs the same function as that ingredient. (Walker, par. 370.) A patentee is always entitled to equivalents regardless of whether or not he has broad claims to cover them. One of the very few chemical cases clearly illustrating this doctrine is *Treibacher vs. Roessler & Hasslacher*, 219 Fed., 210. Here the claim covered a "pyrophoric alloy containing cerium alloyed with iron, substantially as and for the purposes described," while the specification stated that nickel or cobalt and their equivalents might be used in place of iron, there being, however, no broad claim to cover such equivalents. The court held that Mg was an equivalent of iron and accordingly a cerium:magnesium alloy infringed the claim. This same doctrine is supported in the mechanical cases, such as *Weinans vs. Denmeed*, 15 Howard, 341; *Bundy vs. Detroit*, 94 Fed., 524-538; *Metallic Co. vs. Brown*, 104 Fed., 345; *Soehner vs. Stove Co.*, 84 Fed., 185; *Vrooman vs. Penhollow*, 179 Fed., 296; *Whitin Machine Works vs. Houghton*, 178 Fed., 444.

Species on the other hand are not equivalents, and therefore comprehensive claims are needed to cover them. (*Monroe vs. McGreer*, 81 Fed., 954.) Species are distinct inventions and involve patentable differences. "No range of equivalents can overcome a patentable difference." (*Cheatham Electric vs. B.R.T.*, 238 Fed., 172.) In *re Ellis* the various cyclic CH₂ hydrocarbons constituted distinct species and therefore a broad claim was needed in order to cover them.

With regard to the third point of in *re Ellis*, the question arises as to how far the court will go in reading the specification into the claim, in case the claim is met by the prior art or is too broad in view of the fact that some of the members of the broad class have been shown to be inoperative. The answer is that if the patentee in his specification indicated that he intended to claim broadly the court will hold

him to it and the claim will be void absolutely. In *Cambria Iron Co. vs. Carnegie Steel Co.*, 96 Fed., 850, the patentee claimed a process of mixing molten metal and indicated that he intended to claim broadly, and the court so considered it. In this connection it may be stated that the courts will read the specification into a claim where a non-patentable function has been claimed and the specification describes as essential the element which was functionally claimed (*Westinghouse vs. Boyden*, 170 U. S., 537); or where an essential subordinate feature was omitted in the claim (*Lamb Knit Goods vs. Lamb Glove Co.*, 120 Fed., 267); or where a subordinate essential element was omitted in the claim (*Walker*, par. 182; *Wellman vs. Midland Steel Co.*, 106 Fed., 221), but where the specification shows that the patentee deliberately intended to claim broadly the claim will be construed broadly and will not be restricted for the purpose of escaping anticipation or invalidity (*Empire Circuit Co. vs. Channon*, *supra*, and other cases cited in the beginning of this article; *General Sub Construction Co. vs. Netcher*, 167 Fed., 549). The court indicated in *re Ellis* that in the event of finding any of the members of the class of cyclic CH_2 hydrocarbons inoperative, the claims would be restricted to the substances named in the specification and their equivalents. This was because *Ellis* intended to cover in his claims only his described substances and their equivalents.

The question arises, What would *Ellis* be entitled to in the way of equivalents? Would he be entitled to every cyclic CH_2 hydrocarbon not mentioned by him which was found operative? The answer seems to be that where experimentation is necessary to determine which members are operative and which members are not, the patentee cannot cover such members in his claims unless he has mentioned them in his specification. (*Matheson vs. Campbell*; *Rickard vs. DuBon*; *Bracewell vs. Passaic Print Works*.)

PATENTEE SHOULD HAVE BENEFIT OF HIS RESEARCH

These decisions are not quite conclusive, however, for in each of these cases only a few members of a large class were described in the specification. It is believed that where a patentee describes a large number of members of a class, such as in *re Ellis*, he should be entitled to every operative member of that class, even though some members are later found to be inoperative. The reason for this will be clear when we consider that it very often requires considerable original research and thought to conceive and work out a broad class for a particular process or composition, whereas the inventive skill necessary to experiment with various members of the class when once an earlier inventor has already broken the ice and opened up the class will be much inferior to the inventive act of the inventor of the class. In fact it hardly appears to amount to invention at all to determine experimentally what members of a class once discovered are operative or inoperative, for the average skilled chemist could readily perform the task. Where no invention is required to discover a new member of a known and patented class, it is to be considered an equivalent of the members described by the patentee. (*Read Holliday vs. Shulze-Berge*; *American Sulphite vs. Howland Falls*, *supra*.) Such equivalents discovered subsequent to the date of a patent would be covered even by its specific claims and therefore the patentee should have the right to draw claims to cover

broadly any subsequently discovered equivalents. There is no decision, however, clearly giving him this right. The nearest case is *Minerals Separation Co. vs. Hyde*, 242 U. S., 261, where different ores were treated and different preliminary tests were necessary to determine the amount of oil needed and the extent of agitation. The court said: "The process is one for dealing with a large class of substances and the range of treatment within the terms of the claims, while leaving something to the skill of persons applying the invention, is clearly sufficiently definite to guide those skilled in the art to its successful application."

CASES ON CHEMICAL EQUIVALENTS

It will therefore be apparent that the claims of a patent, however broad, cover only the substances described in the specification and their equivalents. (*Hall Borchert vs. Ellenam*, 213 Fed., 341.) The patent covers only such substances not described therein which the average skilled chemist at the date of the patent knew to be equivalents of the substances described (*Heath vs. Unwin*, 2 Web., 236), and such equivalents as might be discovered later without the exercise of invention. (*Read Holliday vs. Shulze-Berge*; *American Sulphite vs. Howland Falls*, *supra*.) It is not sufficient to show that a substance unknown at the date of the patent proves by tests to be an equivalent, if invention was exercised. (*Paint Co. vs. Bird*, 175 Fed., 346.) Generally the issuance of a patent negatives the fact of equivalency where it is contended that the substance claimed in the patent is an equivalent of previously patented substances. (*American Sulphite Pulp vs. Hinckley Co.*, 217 Fed., 57, where a claim for an acid-resisting lining of cement was held not infringed by a new composition claimed in a subsequent patent, the new composition being unknown at the date of the first patent.) Where an ingredient substituted for a substance mentioned in the patent performs the required function better than the patent ingredient and in a different manner it may still be an equivalent. Thus, a claim covering dynamite made from infusorial earth and nitroglycerine was infringed by an equivalent explosive made from mica and nitroglycerine, although mica did not absorb the nitroglycerine like the infusorial earth and as a result produced a more powerful explosive. (*Atlantic Giant Powder Co. vs. Mowbray*, 2 Bann. & Ard., 447.) Where a patentee fails to obtain results with a certain substance he cannot claim it as an equivalent; thus where an inventor was unsuccessful with mica he could not cover it as an equivalent of the glass which he described and claimed broadly as "non-porous vitreous material." (*Folger vs. Dow Electric Co.*, 133 Fed., 295.) Where a patentee intentionally avoids a certain substance, the composition which includes it is not an equivalent and does not infringe. Thus where a patentee claims a disinfectant consisting of camphor oil containing HCHO and states that no water should be present, it is not infringed by a disinfectant containing aqueous formalin and eucalyptus oil. (*Orr vs. Aschenbach*, 225 Fed., 71.)

In *Tilghman vs. Proctor*, 102 U. S., 730, saponification by lime water at a low temperature and pressure was held equivalent to saponification by water at a high temperature and pressure.

In *Miami Copper Co. vs. Minerals Separation Co.*, 244 Fed., 752, the patentee formed a froth by mechanically beating air into mineral pulp containing under

1 per cent oil by means of a mechanical beater and he referred to this process in his claim by the broad term "agitating." The alleged infringer formed a froth by bubbling air through a column of pulp, the resulting agitation being mild and not mechanical. The two processes were held equivalent to each other.

In *Hoskins Manufacturing vs. General Electric*, 212 Fed., 422, an alloy of nickel 65 per cent, chromium 12 per cent, iron 15 per cent and manganese 8 per cent was held to infringe a resistance element composed of a nickel:chromium alloy upon the theory that the addition of the iron and manganese did not materially change the alloy as a resistance element.

In *Gordon vs. Turco-Halvah Co.*, 233 Fed., 430, the claim specified peanut butter, but the specification stated that oily matter generally might be used, and the court held that maize oil was an equivalent. In a second patent in this suit the claim specified cottonseed oil and the specification described no equivalents nor said anything about them, and the court limited the claim to cottonseed oil. The restriction of the claim in the second patent seems to have been rather severe.

If a patentee in his effort to avoid claiming too broadly should unnecessarily restrict his claims, the court will construe them disregarding the limitation, provided the specification shows that the limitation pertains to the operative environment rather than to the inventive step and the limitation does not import a function which the patentee considered important or essential. (*D'Arcy Spring Co. vs. Marshall Mattress Co.*, 270 O. G., 347; *Arnold Creager vs. Barkwill*, 246 Fed., 441; *Loraine vs. General Electric*, 198 Fed., 100.) Where the Patent Office rejects a claim and the applicant accepts a more restricted claim, he is bound by it, although he may have unduly restricted. Where a claim is clear there is no room for construction and the patentee cannot be heard in court to contend for that which he unnecessarily surrendered in the Patent Office in avoiding a rejection. (*United States Glass Co. vs. Atlas Glass Co.*, 88 Fed., 493.) In such cases he is, however, still entitled to equivalents and is not exactly pinned down to the exact language of his claims. (*Consolidated Roller Mill vs. Coombs*, 39 Fed., 25.) It might be mentioned in this connection that a chemical product claim is not limited to the product of the process described, even though that is the only known process. (*Maurer vs. Dickenson*, 113 Fed., 870.)

Electrolytic Zinc in England

Great Britain has never been self-sufficient in zinc production. For instance, in 1913 the production was 60,000 tons and the consumption 220,000 tons. During the past five years the annual production had been 50,000 tons, against a consumption of 180,000 tons. Today its zinc industry is sorely depressed and is operating at less than 20,000 tons per annum since the recent closure of all the large smelters in South Wales. Although British supplies of high-grade ores are important, they cannot be mined and distilled at present prices for spelter. In fact, Germany is the only country which can produce at a profit, solely due to the depreciated exchange. Samuel Field has recently read a paper before the Faraday Society stating that the electrolytic process can now be regarded as a commercial possibility, in view of the fact that it can handle low-grade ores and recover other metals contained as a byproduct. Power in large blocks was to be had in

1917 for 0.34d. per kw.-hr. ($\frac{3}{4}$ c.) and probably would not go above that if the works were placed near the collieries. There are actually large bodies of complex zinc ores within close reach of certain Scotch collieries, making almost ideal conditions. The cost should then be, in a 10-ton plant, using three-stage purification, and labor at 10s. per 8-hr. shift (30c. per hr.):

	£	s.		£	s.
Calcination	2	00	Supplies	1	00
Power	5	11	Salaries and wages.....	4	10
Reagents	3	00	Interest and depreciation.	3	00
Melting cathodes.....	1	10			
			Total	20	11

Or \$100 per long ton.

With a concentrate of 40 per cent Zn, 10 per cent Pb and 5 oz. silver, delivered at £5 per ton, and crediting byproducts recovered, the total cost of zinc should not be more than £24 per long ton (5.2c. per lb.).

While no plans for large-scale production are under development, the British Metals Extraction Co., Ltd., has a small plant in operation near Swansea, South Wales. It is on somewhat more than a laboratory scale, having made about 100 tons zinc, and accumulated valuable information necessary for tonnage production.

Graphite Industry in 1920

The quantity of domestic flake and amorphous graphite sold by producers in the United States in 1920 amounted to 9,510 short tons, an increase of 28 per cent over the quantity sold in 1919.

The value of the graphite sold in 1920 was about \$626,201, as compared with \$778,857 in 1919. These figures are based on reports made by producers to the U. S. Geological Survey.

Operators in Colorado, Nevada and Rhode Island reported sales of 4,694 short tons of amorphous graphite in 1920 at an average price of \$10.60 a ton. This was \$3.52 per ton less than the average price in 1919.

The sales of crystalline graphite in 1920 amounted to 9,632,360 lb., valued at \$576,443, as compared with 8,086,191 lb., valued at \$731,141, in 1919. The average price per pound in 1920 was 5.9c.; in 1919 it was 9c. Alabama led in the production of crystalline graphite, the sales in 1920 amounting to 4,894,648 lb., or 51 per cent of the total quantity sold.

The sales reported from New York and Pennsylvania amounted to 3,552,687 lb., or 37 per cent of the total in the United States, and the remaining 13 per cent was reported from California, Montana and Texas.

The Acheson Co. reported the sale of 7,399,749 lb. of artificial graphite made at Niagara Falls.

DOMESTIC GRAPHITE SOLD IN 1915-1920

Condensation of Zinc Vapor*

A Zinc Retort and Separate Condenser Were Maintained Under Close Temperature Control, and the Amount of Zinc Dust Determined When Condensing It From a Stream of Carbon Monoxide, Water Vapor or Nitrogen

BY OYSTEIN RAVNEP

AS IS well known, zinc is generally produced by heating and reducing zinc oxide by means of carbon. At the high temperature employed the metal is distilled and the vapors condensed. However, the vapor is not completely liquefied, but part of it is deposited as a finely divided powder (zinc dust), which entirely lacks the properties of metallic zinc.

Lately, electric power has been advantageously used for producing zinc. In this case also the oxide is reduced by means of carbon, but the heat is supplied by an electric current. This process has many advantages, but the formation of a considerably greater amount of dust apparently cannot be avoided. Thus a roasted ore with 20 per cent Zn will give almost exclusively dust, ore with 40 to 50 per cent Zn will give equal amounts of zinc and dust, and ore with 60 to 70 per cent Zn will give two parts zinc to one part dust.

As zinc dust has not even approximately the same value as metallic zinc, it is generally returned to the furnace, charged together with the ore and the process repeated. The spelter thus obtained is sometimes distilled again in order to obtain pure zinc. We have therefore two distillations, and consequently the formation of dust twice during the complete process.

Very few systematic investigations have been made to determine the cause of the formation of zinc dust. Early investigators have noted (for instance, at the Belgian smelters, where closed retorts are used) that the formation of dust is more conspicuous at the beginning of distillation. At that time gases are evolved from the charge, and the zinc vapors therefore become more diluted. It has also been shown that the temperature of the condenser influences the formation of dust.

EXPERIMENTAL PROCEDURE

It was the purpose of the following tests to show as far as possible what results might be expected when distilling zinc under various technically possible conditions. Tests were therefore made to distill zinc in various gases and with various condensing temperatures. Many tests have been made particularly with carbon monoxide, as this gas is always present in great quantities, according to the reaction

Zinc from an electric furnace was used, guaranteed to contain 99.9 per cent Zn. The following impurities were found: Pb 0.073 per cent, Cd 0.018 per cent, Fe 0.005 per cent, As 0.003 per cent; total 0.099 per cent.

The tests were made in such a way that a definite, weighed amount of zinc was introduced in a porcelain boat into an electric tube furnace, heated to 915 deg. C.

The furnace (Fig. 1) was provided with entrance and exit tubes for the gas, a Le Chatelier pyrometer (T), and was connected with a receiver for condensation of the zinc vapors.

The furnace consisted of a steel pipe, wound with resistance wire and covered with insulating material. The pipe was tightly closed at one end; the other end was provided with a flange. As will be seen from Figs. 1 and 2, the furnace was closed with a steel plate provided with an asbestos plug of such a length that the temperature of the muffle was kept constant at 915 deg. C.

The condensing receiver was arranged so that the vapors entered a glazed clay cylinder, at the bottom of which the liquid zinc was collected in a porcelain crucible. The dust was deposited in the chamber around the crucible, and such of it as escaped from the cylinder was collected in a bottle with glass wool, and in a U-tube containing a little glycerine to keep the air out. The clay cylinder was closed at the top

FIG. 1. SKETCH OF EXPERIMENTAL RETORT AND CONDENSER

with a tight-fitting asbestos plug. It was also provided with a Le Chatelier pyrometer (T) and was heated in an electric crucible furnace.

The results from the tests may suitably be arranged in the following groups:

Group 1 comprises:

1. The influence of the dilution of the zinc vapors on the amount of dust.
2. The influence of the carbon monoxide on the formation of dust at various velocities of the gas and temperatures of the condenser.

Group 2 comprises the influence of moisture (steam) on condensation.

Group 3 comprises the influence of nitrogen on condensation of zinc.

DILUTION OF ZINC VAPOR

Thirty liters of carbon monoxide was used for each test. It was made from potassium ferrocyanide and

*Translated from *Tidsskrift for Bergvaesen*, 1919, No. 10, p. 121. Portions of a dissertation prepared at the Institute of Inorganic and Physical Chemistry, Dr. P. Farup, director, Technical High School of Norway.

TABLE I.				
Test	Velocity of of the CO Stream, c.c. per Min.	Amount of Zinc in the Receiver, g.	Amount of Dust, g	Dust, per Cent
1	0	16.75	0.18	1.07
2	5	17.42	0.34	1.95
3	10	28.48	0.56	1.97
4	20	25.52	1.42	5.56
5	30	26.60	2.05	7.71

concentrated sulphuric acid, metered and passed through potassium hydroxide, calcium chloride and concentrated sulphuric acid. The amount of zinc used was 30 g.

Table I shows the results from the first series of tests with the condenser at a constant temperature of 470 deg. C. In the first test the furnace temperature was 940 deg. C. (20 deg. above the boiling point of zinc); in the others, 915 deg. C. That is to say, the first experiment represents distillation of zinc under atmospheric pressure of its own vapor. It is evident from the test that the more dust that is obtained the more diluted the zinc vapors are.

Now the laws in regard to the condensation of zinc vapor are the same as the laws for condensation of gases in general. If a given amount of saturated zinc vapor is contained in a chamber, the walls of which have a lower temperature than the vapor, metallic zinc will precipitate along these walls. If the walls have a temperature below the melting point of zinc (418.2 deg. C.) the metal will be deposited as a finely divided solid. If, on the contrary, the temperature of the walls is above the melting point of the metal, liquid zinc will be obtained, and the condensation will continue until the pressure of the zinc vapor has dropped to that value correct for the prevailing temperature. When this condition has been reached, the condensa-

FIG. 2. AMOUNT OF DUST MADE WHEN CONDENSING ZINC FROM A STREAM OF 10 C.C. CO PER MINUTE

saturated with zinc vapor. In other words, saturated vapor is simply a gaseous substance in equilibrium with its liquid or solid phase.

Therefore, as a given quantity (30 g.) of zinc vapor is condensed, liquid zinc is formed, the amount of which for a certain temperature of the condensing receiver is greater the less diluted the vapor.

HIGH CONDENSER TEMPERATURES

Table II and the curve Fig. 2 show the results from the second series of tests with increasing temperatures in the condenser, but with a constant velocity of

CO ₂ , per cent.....	3.6	3.9	5.2	7.1	8.2
CO, per cent.....	95.2	95.4	94.5	94.4	91.2
Remainder, per cent.....	1.2	0.7	0.3	0.5	0.6
ZnO in dust, per cent.....	3.82	3.79	4.21	4.54	5.60

velocity of carbon monoxide of 20 c.c. per min. The only difference from the preceding series of tests is the fact that the velocity of the carbon monoxide is twice as great; 30 liters of carbon monoxide and 30 g. of zinc were used for each test. The furnace temperature was 915 deg. C.

As shown graphically in Fig. 3, the amount of dust increases with the temperature of the condenser, when this is above the melting point of zinc. Curve 3, also shows in comparison with Fig. 2, as the first series of tests did, that the amount of dust increases with the dilution.

MINIMUM DUST FORMATION

Both the curves (Figs. 2 and 3) show clearly that the minimum amount of dust is obtained when the temperature of the condenser is the same as the melting point of the metal. This fact may be explained as follows:

When the temperature of the condenser is below the melting point of the metal, the zinc will be condensed in a finely divided, solid state (dust), and the amount of this dust will increase with decreasing temperature. That the amount of dust increases with increasing

temperature in the condenser above the melting point of the metal may be due to the fact that zinc acquires a perceptible vapor pressure as soon as the melting point has been passed.

According to Clausius, the vapor pressure of the zinc

FIG. 3. AMOUNT OF DUST MADE WHEN CONDENSING ZINC FROM A STREAM OF 20 C.C. CO PER MINUTE

may be determined for any temperature, as soon as it is known for one certain temperature. We have:

$$\frac{d \ln p_1}{dT} = \frac{L}{RT_1^2} \quad (1)$$

Here p denotes the vapor pressure, and L the molecular latent heat of vaporization at absolute temperature T_1 . R is the calorimetric gas constant = 1.985.

By integrating equation (1) we obtain:

$$\ln p_1 = -\frac{L}{RT_1} + C \quad (2)$$

If we now know the pressure of the zinc p_2 at a corresponding temperature T_2 , the constant C may be determined.

$$\ln p_2 = -\frac{L}{RT_2} + C$$

By inserting this value for C in equation (2) we obtain, when we assume L to be constant between the temperatures T_1 and T_2 :

$$\ln p_1 = \ln p_2 - \frac{L(T_2 - T_1)}{RT_1 T_2}$$

or

$$\log p_1 = \log p_2 - \frac{L(T_2 - T_1)}{2.3RT_1 T_2}$$

Schenck¹ finds p_2 to be 10 mm. at 582 deg. and $L = 27,670$ cal. From these data and the preceding

TABLE IV. FOUND AND CALCULATED VALUES OF AMOUNT OF ZINC DUST

Test (Table II)	Temp. of Receiver	Amount of Dust Found, g.	Calculated	
			Amount Uncondensed Zinc, g.	The Zinc Pressure, m.m.
4	430	0.30	0.031	0.29
5	470	0.56	0.096	0.89
6	520	1.82	0.297	2.79
7	600	1.84	1.539	14.00

equations the pressures for other temperatures may be calculated as in Table IV.

The amount of uncondensed zinc is calculated as follows.

At 430 deg. the vapor pressure of zinc is 0.29 mm. and that of the carbon monoxide 760 — 0.29 = 759.71 mm. Therefore, for one volume of carbon monoxide

which leaves the receiver, $\frac{0.29}{759.71}$ volumes of zinc vapor escape. Thirty liters of carbon monoxide at 20 deg. was used for the test. At 430 deg. its volume will be:

$$\frac{30(430 + 273)}{20 + 273} = 71.98 \text{ liters CO}$$

The zinc escaped is therefore:

$$\frac{0.29 \times 71.98}{759.71} = 0.0275 \text{ liter zinc vapor}$$

at 430 deg. and 760 mm. pressure.

Reduced to 0 deg. and 760 mm., it will be:

$$\frac{0.0275 \times 273}{430 + 273} = 0.0107 \text{ liter zinc vapor}$$

As zinc in the gaseous state is monatomic, 22.4 liters of zinc vapor at 0 deg. and 760 mm. corresponds to 1 gram-atom of zinc or 65.37 g.; 0.0107 liter of zinc vapor therefore corresponds to 0.031 g. zinc.

It will be seen from Table IV that the actual amounts of dust produced are greater than the calculated values of uncondensed zinc. This may be because more zinc is taken along with the gases than the amount corresponding to the vapor pressure of the metal at the temperature in question. However, to judge from the tests, the principal cause of high dust production seems to be some subsidiary chemical reactions.

The gas analyses in Tables II and III show that the percentage of carbon monoxide in the gases, as well as the amount of zinc oxide in the dust, increases with the temperature of the receiver. It may therefore be assumed that the carbon monoxide is split up according to the formula:

During the condensation, small drops of zinc are formed, and if now carbon dioxide is present, according to (3), a film of zinc oxide may be formed around these, according to the formula:

This film will prevent the separate drops from running together; they follow the stream of gas, and are collected as dust.

As is evident from Tables II and III, it was not possible to obtain the total amount of zinc in the condenser. It was discovered that the greater part of this amount lacking was deposited in the pipe leading from the furnace; after every test it needed to be removed by drilling.

This mass of zinc was not distributed along the whole pipe, but had settled on only a part of it where the temperature during the test had been between approximately 800 and 700 deg. Further down, where the temperature had been lower, no zinc had been deposited. It was also seen that the mass contained not only metallic zinc but also zinc oxide and carbon. The explanation is advanced that at 700 to 800 deg. the reaction velocity of $2\text{CO} = \text{CO}_2 + \text{C}$ is particularly high, with a corresponding high production of ZnO on the condensate. Carbon and zinc oxide are therefore formed, which, together with some liquid zinc, cause the obstruction such as often occurs at electric spelter furnaces.

The gas stream is gradually cooled as it passes on, and the reaction velocity of $2\text{CO} = \text{CO}_2 + \text{C}$ decreases,

¹Physikalische Chemie der Metalle.

not only on account of the lower temperature, but also because a little carbon dioxide is now present.

INFLUENCE OF MOISTURE ON CONDENSATION

These experiments, to determine the influence of moisture on condensation, were made in such a way that carbon monoxide was passed through wash bottles containing water, which at each test were kept at a definite temperature.

The percentage by volume of water vapor in the gas may be calculated as follows: When carbon monoxide is passed through water of a certain temperature and is in contact with the water a sufficient time, it will absorb a definite amount of water vapor, corresponding to the pressure of the water at the prevailing temperature.

The resulting gas mixture will consist of $\frac{x}{760}$

volumes of water vapor, and $\frac{760 - x}{760}$ volumes carbon

monoxide, where x signifies the pressure of the water at the temperature used.

At 2 deg. water has a vapor pressure of 5.302 mm.

At 20 deg. it has a vapor pressure of 17.391 mm.

At 45 deg. it has a vapor pressure of 71.311 mm.

Table V shows the results from these tests. The temperature of the condenser was 430 deg. C., and the

TABLE V. INFLUENCE OF WATER VAPOR ON CONDENSATION

Test.....	1	2	3
Temperature of water in the wash bottles, deg. C. . .	2	20	45
Per cent by volume of water in the gases entering the furnace.....	0.69	2.29	9.39
Amount of zinc in the condenser, grams.....	23.25	17.0	8.0
Dust in the condenser, grams.....	1.56		
Dust, per cent.....	6.63		
ZnO in dust, per cent.....	10.51		

velocity of the gas 20 c.c. per min. The furnace temperature was 915 deg., and the amount of zinc used was 30 g.

By comparing Experiment 1 (6.63 per cent dust) with Experiment 3 in Table III (1.49 per cent dust), it will be seen that even a small amount of moisture considerably increases the formation of dust. The tests show also that the higher the content of water in the gases the less zinc will be deposited in the receiver. It will be partly oxidized before entering, and will settle as oxide along the walls, so that the furnace finally will be clogged up. In Experiments 2 and 3 the zinc in the condenser was completely covered with oxide.

When making zinc on a large scale, the charge should therefore be as free from water as possible.

INFLUENCE OF NITROGEN ON CONDENSATION

Commercial nitrogen was first passed over copper, heated to a red heat, and then through concentrated sulphuric acid. The furnace temperature was as before, 915 deg., and the temperature of the condenser was 430 deg. Thirty grams of zinc and 30 liters of nitrogen were used for the test. The nitrogen was passed through the apparatus with a velocity of 10 c.c. per min. There was found in the receiver 16.20 g. zinc, very brittle and of gray color. As the distillation had taken place in an atmosphere containing nitrogen, the zinc was dissolved in 30 per cent sulphuric acid and analyzed for nitride, Zn_3N_2 . The solution was boiled with potassium hydroxide in a Kjeldahl apparatus, and the ammonia formed was absorbed in N/10 sulphuric acid. For 16.20 g. zinc 2.3 c.c. N/10 sulphuric acid was used—i.e., it contained 0.16 per cent nitride.

The zinc which was drilled out from the pipe between the furnace and the receiver was found to contain 0.14 per cent nitride. A blank test was run on the potassium hydroxide, finding it nitrogen free.

Another test conducted in the same way as No. 1, but with 20 c.c. nitrogen per min., gave 23.65 g. zinc in the condenser and 1.78 g., or 7.51 per cent dust.

For 23.65 g. zinc 3.2 c.c. N/10 sulphuric acid was used—i.e., nitride = 0.31 per cent.

ZINC NITRIDE

As mentioned above, the zinc was brittle and of a dull gray color. This may be due to the nitride. In the periodic table of the elements, the properties of any one element are determined by the properties of the elements in the same groups and series. Zinc will be found in the same group as beryllium, magnesium and calcium and close to aluminum in the following group. All these metals react easily with nitrogen, forming nitrides. Zinc nitride is described in the literature as a gray powder which is easily decomposed by water:

In another test, three pieces of zinc, weighing in all 30.5 g., were heated in the furnace to 640 deg. Nitrogen was passed through the furnace during the heating as well as the cooling, and it was found at the end that the zinc pieces were still in the porcelain boat and had not run together, even though zinc melts at 418.2 deg. They were, instead, covered with a gray powder, which formed a film around each one. The nitrogen had therefore attacked only the surfaces of the zinc pieces and later protected them from further action. An analysis of the fragments gave an average of 0.70 per cent nitride.

As the pieces had not run together, it is reasonable to assume that the reaction between the nitrogen and the zinc had begun below the melting point. In the Norwegian patent 23,165, "Synthetic Production of Ammonia From Its Elements," it is stated that ammonia is formed when nitrogen and hydrogen are passed over zinc at a temperature below the melting point of the metal. According to this patent, the zinc will act as a catalyst as low as 200 deg. C. To judge from the tests, it is therefore not impossible that in the above-mentioned ammonia process a nitride is first formed on the surface of the zinc and that it is this which facilitates the combination between the two elements.

One further finds in *Chemisches Centralblatt*, 1916, vol. 2, No. 2, that dry gaseous ammonia reacts with zinc dust and forms nitride. The most favorable temperature is 600 deg. C., and a product with up to 10.6 per cent nitrogen is obtained; since Zn_3N_2 corresponds to 12.5 per cent N, the end product contained 85 per cent nitride. As nitride has a high dissociation pressure at its temperature of formation and it is therefore difficult to obtain it entirely free from zinc, the substance may be assumed to be a mixture or solid solution of $\text{Zn}_3\text{N}_2 + x\text{Zn}$.

The phase rule will throw some light on the relationship between metal, nitride and gaseous nitrogen. If we have three phases, liquid metal, solid nitride and a gaseous phase ($p = 3$), and two components, zinc and nitrogen ($N = 2$), then

$$F = N + 2 - p \\ = 2 + 2 - 3 = 1$$

That is to say, there is one degree of freedom. When

the nitride has a certain nitrogen pressure, equilibrium will be attained when this pressure corresponds to a definite temperature, and the concentration will adjust itself simultaneously.

If, however, the nitride is dissolved in the liquid zinc, then the number of phases is reduced to two, and F equals 2. Regarding the temperature constant, the pressure and concentration may change until the solution becomes saturated. Further formation of nitride will then cause the system to revert to monovariance. $F = 1$ is therefore valid only in case the nitride takes part in the reactions as an independent phase.

If, therefore, nitrogen is passed over finely divided zinc at 600 deg., as in the above-mentioned tests, nitride will continue to be formed until the nitrogen pressure of the mixture $Zn_3N_2 + xZn$ equals the partial pressure of the nitrogen in the stream of gas.

Zinc dust from an electric spelter furnace, as well as dust from an electric refining furnace, was next examined for nitrogen. It was shown that the spelter dust contained 0.34 per cent nitride, and the refined zinc dust contained 0.33 per cent nitride. It has been shown in *Chemisches Centralblatt*, 1911, vol. 2, that zinc dust generally contains 0.16 to 0.42 per cent nitride. Consequently it has been demonstrated that zinc reacts with any nitrogen which may be present in the retort, and nitrogen should consequently be kept out of the apparatus as far as possible.

Regarding the influence of sulphur, it may be mentioned that the zinc dust from an electric spelter furnace contained 0.95 per cent S, which was present in the form of sulphide. Prof. J. Vogt has shown that zinc sulphide is appreciably volatile at 1,400 deg. In an electric furnace the temperature may run so high, as the slag produced is ordinarily tapped liquid.

Now, if the zinc ore is poorly roasted, so that the charge contains sulphur, some sulphide will volatilize. It will accompany the gases in a finely divided state, and may provide condensation nuclei which will promote the formation of dust.

SUMMARY

The results thus found may be summarized as follows:

1. The amount of dust (for a given temperature of the condenser) is greater the more dilute the zinc vapor.

2. When condensing zinc, the temperature of the receiver is of paramount importance, since zinc is appreciably volatile above its melting point.

In practical work, it is difficult to keep the temperature exactly at the melting point of the metal, and the tests confirm the idea (Tables II and III, Figs. 2 and 3) that it is better to keep the temperature rather a little above than below the melting point.

3. The zinc vapors should have as short a path as possible from the furnace to the receiver. The longer time the zinc vapors require in order to be condensed the more carbon dioxide will be formed, according to the equation $2CO = CO_2 + C$ and the greater the amount of dust.

4. Even small amounts of water vapor in the gases promote the formation of dust and the precipitation of zinc oxide in the channel leading from the furnace to the condenser.

5. As nitrogen reacts with zinc, the reducing agent should contain as little nitrogen as possible. Moreover, the apparatus should be as tight as possible in order to keep the air out.

6. The various materials going into the charge should contain as little sulphur as possible, as it may cause the formation of zinc sulphide, which may volatilize at electric furnace temperatures. Some zinc sulphide may also remain in the charge, so that in any case some zinc will be lost.

Organization of Employers in Germany*

THE employers in German industry were extensively organized even in pre-war days. The auxiliary service law¹ (*Hilfsdienstgesetz*), enacted at the end of 1916, which had for its scope the greatest possible exploitation of all the economic forces of Germany, was responsible for the creation of additional large employers' organizations. Since the termination of the war, organization of the workers and salaried employees has made phenomenal progress and the solidarity of the workers is pushing the employers toward the utmost limits of financial concessions without securing afterward any compensation by way of increased or improved production. It is therefore not to be wondered at if employers' organizations have increased in numbers during the last two years and show a great tendency to combine in powerful national central organizations (*Reichsverbände*) so as to be able to resist in closed ranks the ever-increasing demands of the worker. Constantly repeated wage fights have created an atmosphere of bitterness, and since the fight has been transferred exclusively into the material domain employers' and workers' organizations face each other with an alarming incapacity for comprehending the true nature of problems for which a solution ought to be searched in common.

DIVISION OF THE ORGANIZATIONS

German employers' organizations may be divided into four groups, according to whether they chiefly concern themselves: (1) With general economic and political problems; (2) with general socio-political problems; (3) with the regulation of special business interests (regulation of production, sales, or prices); or (4) with the safeguarding of the special interests of the employers in their relations with the workers (regulation of working conditions, especially of wages and hours of labor). Some employers' organizations include among their activities several or all of the four tasks enumerated. Employers' organizations are organized by industry groups as national, state, district or local.

STATISTICS ON THE ORGANIZATIONS

The latest official statistics on employers' organizations published by the German statistical office cover the year 1918 and are very incomplete owing to conditions prevailing during the war.

Statistics covering the year 1915 show that 3,683 employers' organizations were in existence in Germany in that year. Of these, 125 were national organizations, 499 were state or district organizations, and 3,059 were local organizations. Of the total number of organizations 1,920 reported a total of 156,938 members and 1,366 organizations reported the number of workers employed by their members, the tabulation of which

*From *Monthly Labor Review*, vol. 12, No. 3, March, 1921, p. 129.

¹See *Monthly Labor Review*, April, 1918, pp. 89-103.

resulted in a total of 4,281,477 workers. By the end of 1918 the number of national employers' organizations had increased to 839, the following industry groups having the largest number: Commerce, 149; metal-working industries, 141; textile industry, 86; clothing industry, 56; quarrying, stonecutting, excavating, etc., 51; chemical, 51; paper, 51.

NATIONAL FEDERATION OF GERMAN INDUSTRY AND UNION OF GERMAN EMPLOYERS' FEDERATION

The strongest national organizations are the National Federation of German Industry (*Reichsverband der Deutschen Industrie*), founded in Jena on Jan. 12, 1919, through the consolidation of several large organizations covering various industry groups and intended as a solidary central organization of German industry for the representation of its political and economic interests, and its counterpart, the Union of German Employers' Federations (*Vereinigung der Deutschen Arbeitgeberverbände*), which deals with all social and socio-political problems of the German industry. One hundred and thirty national federations were affiliated with the latter organization in January, 1920. The number of workers employed by the members of these affiliated organizations is given as exceeding 4,000,000. The union has strongly opposed all attempts of workers' organizations to secure for the workers a share in the management of the establishments and was largely responsible for the mild form given to the German works' council law, believing that increased production is absolutely necessary for the economic reconstruction of Germany and that increased production can be achieved only by an independent employers' class and the development of free initiative by the employers.

At the last annual meeting of the Union of German Employers' Federations (March 11, 1920, at Berlin) its secretary pointed out "that a large number of social problems are awaiting solution, but that the union should for the present center all its activities upon the solution of the wage problem, the adjustment of prices, and consequently also of wages to world's market prices, the building up of a wage system based on the cost of living, the introduction of sliding wage scales, consideration of the size of the family of the worker in the fixing of wages, etc.; that a clearly defined policy of the employers' federations with respect to these problems requires thorough investigation of existing conditions and their effects; that the principal task of the German employers' federations must be energetic co-operation in reconstructing a basis for efficient production. They must create the conditions which make the performance of work possible and must oppose unjustified attempts to disturb and hamper peaceful production. To strengthen and support them therein through the power of combination must now as before be the task and aim of the Union of German Employers' Federations."

OTHER ORGANIZATIONS

The Hansa Union of Trade, Commerce and Industry (*Hansabund für Gewerbe, Handel und Industrie*), one of the most reactionary employers' organizations of Germany, which has always maintained the point of view that the employer must be "master in his own house," has for a long time cherished the idea of forming a superunion of all German employers' organiza-

tions. This idea has in part been realized. According to *Soziale Praxis* (Berlin, July 21, 1920) some of the large national employers' organizations have combined into a Central Committee (*Zentralausschuss*). This central committee has proclaimed as its aim the solidary safeguarding of the common economic and political interests of all German employers and a concerted defense against all movements directed against these interests. A subsequent issue of *Soziale Praxis* (July 28, 1920) states, however, that the formation of this superunion has not been greeted with general acclaim. The fact is that German employers are already much overorganized. For this reason the National Federation of German Industry and the Union of German Employers' Federations have declined to become members of the new Central Committee. These two organizations are much stronger central organizations of employers than the new creation of the ultraconservative Hansabund can ever expect to become.

POWER OF THE GERMAN EMPLOYERS' ORGANIZATIONS

During the present critical industrial and labor situation the German employers' organizations schooled through long experience and welded together in the fire of revolutionary wage movements will give proof of their great power. The Union of German Employers' Federations is strongly prepared for defensive action, as has become evident from a secret circular letter addressed to its members. This circular letter, which somehow came into the hands of some labor organization and was given wide publicity in the labor press, deals with the attitude to be taken by the employers toward the works' council law of Jan. 18, 1920. The letter states that "the plans for a general strike of employers against the enactment of the works' council law have not been carried out, owing to reasons of expediency. It is also not intended to use sabotage against the law. Employers are, however, urgently requested to adopt a strong defensive attitude in the application of the law against all attempts to go beyond the letter of the law made either by the regulations for the enforcement of the law or by the workers. Employers are especially admonished against making concessions in the application of article 62 of the law.³ In the framing of shop regulations (*Arbeitsordnungen*) and in the conclusion of collective agreements employers' federations should not go beyond the bounds of legal obligations." It can only be hoped that this warning will not prevent employers from working in harmony with sensible works' councils, however great the difficulties that are to be overcome while this new German institution is in its experimental stage.

In connection with the subject of employers' organizations it should be mentioned that following the amalgamation of German employers' federations the seventeen existing employers' societies for insurance against strikes formed themselves into one society under the name of German Protective Association Against Strikes (*Deutscher Streikschutz*).

(An article on "Organization of Workers in Germany" will be published in a subsequent issue.)

³Article 62 of the works' council law has the following wording: "A works' council shall not be created, or, if already created, shall be dissolved if, in the nature of the establishment, there are special difficulties in the way of its institution or functioning and if by virtue of a collective agreement declared to be universally binding some other form of representation of the employees of the establishment exists or is to be set up. This form of representation shall take over the rights and duties assigned to the works' council by the present law."

GENERAL VIEW OF THE JONES & LAUGHLIN STEEL CO.'S BYPRODUCT COKE PLANT

Byproduct Coke Plant of the Jones & Laughlin Steel Co.

A Summarized Description of the Installation and Operation of a Standard
Koppers Coke Ovens Plant at Hazelwood, Pa., Capable of Coking
Under Normal Conditions 5,000 Tons of Coal Per Day

BY C. R. MEISSNER

THE byproduct coke plant of the Jones & Laughlin Steel Co. of Pittsburgh, which has now been in operation for nearly two years, includes many new developments in coking and byproduct recovery technique, making it one of the most up-to-date and efficient plants in the world.

The new plant comprises 300 ovens, in five batteries of sixty ovens each. Four of these batteries were built and put into operation first, the fifth being added about nine months later. Construction work was begun in May, 1918, and carried to very rapid completion under stress of war-time demands. The first three batteries started pushing coke in June, 1919, a year after ground was broken, and the fourth was started up in the following September. The fifth battery, of the new triangular-flued design, was started in March, 1920.

As normally operated the plant cokes about 5,000 tons of coal per day.

The entire byproduct coke plant was designed, constructed and put into operation by the Koppers Co. of Pittsburgh.

The plant is located along the Monongahela River at Hazelwood, and practically all coal is received direct from the company's mines. The coal as received is crushed to 4 in. at the mines. The roll crushers at the coke plant are designed to reduce to $\frac{3}{4}$ -in. if desired.

OVENS

There are three batteries in one row placed parallel with two in the other unit, their discharge sides facing

each other. A 3,000-ton coal bin located over each row supplies the coal to the larry cars. Each of these bins is divided into two compartments to allow for cleaning out or repairs without interruption of coal supply.

The ovens are of the standard Koppers cross-regenerative type. The inside dimensions are: length, 37 ft. between doors; height, 9 ft. 10 $\frac{1}{2}$ in.; width, tapering from 18 $\frac{1}{2}$ to 15 $\frac{1}{2}$ in. from coke discharge sides to pusher side. When coking straight high-volatile coals, it has been found of decided advantage to use a narrower oven chamber than that used for coking mixtures with lower-volatile coals.

The larry cars are built with four separate conical hoppers, above which are placed the measuring cylinders. By this method the ovens are always charged to constant volume regardless of weight, due to fineness of coal or moisture, uniformity and regularity being two requisites of good operation. Each larry car is also weighed as a matter of record. Telescopic, adjustable cylinders or sleeves are provided around each of the larry car hopper chutes, which are operated by a handle in the operator's cab. These are lowered to the oven brickwork during charging to prevent coal spillage around the charging holes. A motor-driven metal swab is provided on each larry car for cleaning out carbonaceous deposits in the gas off-take pipes when necessary.

Steam ejectors, provided in the gas off-takes from each oven, are used during charging to draw the first gas into the collecting main and thus prevent its loss

VIEW OF OVENS, SHOWING COAL LARRY, DOOR EXTRACTOR AND COKE GUIDE

to the air through the charging holes, thereby increasing the byproduct yield and making working conditions better for the men.

The first four batteries are built up of standard ovens having the well-known rectangular vertical flue construction in the heating walls. In the fifth battery, however, the heating walls are constructed according to the improved triangular flue design.

In this new type of construction the division walls between the heating flues are made diagonal to the plane of the oven walls, which gives the flues a triangular cross-section. Thus we have two sets of flues in each wall facing in opposite directions toward the adjacent ovens. Similarly each oven has practically its own independent set of heating flues. The overlapping arrangement makes it possible to supply fuel gas from a common header centrally located below the flues; or, in case producer gas is used, through ports from the gas regenerators. There are, however, two separate horizontal flues; one being located at the top of each set of vertical flues for carrying off the products of combustion. Practically independent regulation for each oven is attained by this arrangement. The

BATTERY OF TRIANGULAR FLUE OVENS DURING CONSTRUCTION

accompanying photograph of a battery of triangular flue ovens during construction gives an idea of the flue arrangement. Compared with the rectangular flue construction, this triangular flue development involves no increase in the width of the oven wall, no increase in weight of brickwork and no additional investment per oven.

There are obvious mechanical advantages in this new construction as compared with the rectangular flue type. The triangular bracing gives a much stronger wall. Theoretically this increase in strength as regards lateral pressure is 33 per cent. Actual test models have shown an advantage of 30 per cent. Due to the overlapping arrangement there are forty-four flues in the new wall as compared with thirty in the former type. This tends to give greater uniformity of heating. The faces of the flues adjacent to the oven wall are wider and thus the liner brick are longer, resulting in a 22 per cent decrease in the number of joints in each wall. Less opportunity is thus provided for gas loss outward or air leakage inward and the wear and tear during regular operation are materially reduced.

OVENS, QUENCHING CAR, COKE WHARF AND SCREENING STATION

The operation of the triangular flue type of ovens has proved so satisfactory that the Koppers Co. is installing them in several new plants.

COKE HANDLING

At the quenching stations the drainage water is passed through settling basins and recirculated, river water being used to make up for evaporation. More or less fine sediment, mostly coke breeze, settles in the spray pipes and tends to give trouble due to blocking up the holes from the inside. In order to facilitate the removal of this sediment quick opening valves have been provided at both ends of each spray pipe. Regular flushing out obviates all stoppage troubles. The moisture is readily controlled. Hot coke spots are quenched on the wharf by means of hand hose connections.

All coke-handling apparatus is arranged in duplicate between the two rows of batteries. Ample coke wharf space is provided for each unit of batteries. One wharf will hold eight, the other ten oven charges, so any ordinary delays in the coke-handling system or in spotting cars need not disturb the oven-pushing schedule, which is maintained with iron-clad regularity. A small auxiliary wharf is provided to handle run of coke direct to cars over a separate conveying system in case of any serious trouble in the regular system. The two screening stations are separate and independent,

GAS EXHAUSTER WITH REINFORCED CONCRETE CASINGS

loading cars on parallel tracks. The screens are of the bar grizzly type, set at 28 degrees, each made up of forty-eight bars wide and six sets long, spacing $\frac{3}{4}$ in. The bars are 2 ft. long and the spacing is wider at the bottom than at the top of each set. The bars are made wedge-shaped in section, giving an opening flaring out at right angles to the screen surface. This construction prevents coke pieces from wedging between the bars, making the screens self-cleaning. The increased spacing of the bars as they wear out is taken care of by replacements. Coke cars are at present spotted by steam locomotives, the movements of which are regulated by electric signals from screening stations.

GAS-COLLECTING AND COOLING SYSTEM

The gas-collecting and byproduct-recovery system is of the standard Koppers design. The pressure on the collecting mains is maintained at an average of 2 $\frac{1}{2}$ mm. water gage. By carrying this pressure in the collecting mains, the pressure in top of oven is zero, the same as in the top of the heating flues. Butterfly valves controlling this pressure are located in each of the two suction mains from each battery. These valves are controlled by governors, some of the standard Northwestern type and some of the hydraulic type. Pressure variations affect a float in the usual manner, but this float operates a small hydraulic valve mechanism, which in turn controls the water flow to the operating piston cylinder. Operation is very smooth, positive and also very sensitive. Butterfly dampers are used in the gas off-take goosenecks to cut off the ovens from the collecting main. They are very easy to operate, light deposits of carbon making them fit gas tight, thus proving very satisfactory.

The collecting and suction mains are flushed with a mixture of 40 per cent tar and 60 per cent liquor, this mixture being quite closely controllable by a suitable arrangement of valves and piping at the flushing or hot drain tank. Such a mixture has been found most satisfactory for maintaining clean mains and for cooling the gas. Gas reaches the primary coolers at about 75 deg. C. After the coolers, it is carried at 28 deg. to 30 deg. C. Lower temperatures than this tend to throw down more light oils into the tar than is desirable.

CONCRETE EXHAUSTERS AND BOOSTERS

Due to the shortage of steel during the war period in which the plant was built and to the difficulty in obtaining deliveries, it was necessary to economize on metal where possible. To avoid several months' delay in

securing casings for the centrifugal gas exhausters and boosters, they were constructed of reinforced concrete. They resemble the steel shells in all outward appearances. The base is cast integrally with the foundation. Cast-steel flanges are cast in to make connection with similar flanges on the upper section and to carry the bearing boxes. The top sections are entirely of concrete cast in one piece with steel flanges and eye bolts complete. These machines are giving entire satisfaction under all plant operating conditions. Concrete has previously been used for mine fan casings, but this is believed to be its first trial for high-speed centrifugals, pumping raw gas. The concrete turbo blowers were constructed on the ground by the Koppers Co. under direction of General Electric Co. engineers.

BYPRODUCT RECOVERY APPARATUS

The P. & A. tar extractors are equipped with Tagliabue controls to maintain a constant gas pressure differential by raising or lowering the level of the tar seal. A differential pressure of 6-in. water is normally maintained. As the centrifugal exhausters remove about 75 per cent of the tar remaining in the gas after the primary coolers, the tar extractors function in the removal of the last traces of tar fog. The reheaters are not regularly used but only as required by saturator conditions. This is due to the use of 66 deg. Bé. sulphuric acid. The heat of reaction is sufficient to maintain the bath at a proper operating temperature to evaporate water used in washing salt, etc.

The saturators are of the Koppers large elliptical design with two ejectors and two drain tables feeding to three centrifugal driers. Dried salt is wheeled in buggies and after weighing on a suspended platform scale is dumped into a pit. From this it is periodically removed by an overhead electric traveling crane and bucket and dumped into the stock pile.

TAR-FLUSHING SYSTEM AND AMMONIA STILL WASTE

All condensate from the primary coolers, exhausters, tar extractors, etc., is run directly into the suction of the flushing pumps instead of into the hot drain tank, to be pumped back over the collecting mains. This is done to allow some redistillation of the light oils by the hot gas in the mains, thus cutting down the amount going into the tar and allowing a larger recovery by the light-oil scrubbers. All return flushing from the collecting and suction main goes direct to the hot drain tank. Motor-driven centrifugal tar and liquor pumps are used

INTERIOR OF BYPRODUCT BUILDING, SHOWING AMMONIUM SULPHATE APPARATUS

regularly. A small boom derrick with clamshell bucket is provided for cleaning out the hot drain tank and still waste sump, being located between the two.

The lime sludge from the sump is being successfully used by mixing with the mud used for luting the oven doors. It is said to improve materially the consistency of this mud and at the same time dispense with the loam requirements.

LIGHT-OIL RECOVERY PLANT

There are two final coolers 80 ft. high and 14 ft. in diameter, having the same interior construction as the scrubbers, being fitted with wooden hurdles. The four scrubbers are 100 ft. in height and 18 ft. in diameter, and are placed in parallel sets of two each. The gas is evenly divided through the two sets of apparatus.

DISTRIBUTION OF GAS

The final cleaned gas after leaving the light-oil scrubbers goes to a 40,000-cu.ft. holder. The surplus gas is used in heating furnaces, soaking pits, etc., to replace natural gas formerly used. Total and surplus gas is measured by Venturi meters which give very close and satisfactory results. When the mills do not require the gas, as on Saturday afternoon and Sunday, it is burned in the boiler house or bled to the atmosphere in extreme cases.

BOILER HOUSE

The boiler house contains eight B. & W. 500-hp. boilers equipped with Coxe stokers and Dietrich flat suspended arches. Coke breeze is burned normally, and practically all of the plant production of this material is thus utilized. Breeze is dumped from hopper cars to a pit and thence handled by an overhead crane to the feeder bins at the boilers. Ashes are dumped from hand trucks into an adjacent pit and handled by the same crane to cars for removal.

BENZENE PLANT

The benzene plant embodies many improvements. Heat exchangers, vapor to oil, are mounted directly on

capacity. There are three crude and four pure stills, the only difference being in the greater height of the rectifying columns on the latter. Motor fuel, pure benzene and toluene are run off as the market dictates.

ACID-REGENERATING PLANT

The crude fractions are washed in a separate building located at some distance from the benzene plant. The two agitators are set high in a steel framework and sludge is drained directly into four acid-regenerating pots located below and to one side, but well above the yard level. These pots are of the tilting type with stationary sand-sealed covers. The final spongy sludge mass is dumped directly into large wooden boxes set on a flat car. These boxes are equipped with steel hooks so they can be lifted and emptied by a locomotive crane.

Synopsis of Recent Chemical & Metallurgical Literature

The Edible Vegetable Oil Industry.—A concise outline of the edible vegetable oil industry by H. Tefft was published in the April issue of *Canadian Chemistry and Metallurgy*, p. 102.

Vegetable oils may be divided into two classes, domestic and Oriental. The domestic oils (produced on the North American continent) include cottonseed, linseed, peanut, castor, corn and sunflower. The chief Oriental oils are coconut, palm, palm-kernel, soya-bean, rape-seed and peanut. The Philippine and South Pacific Islands and the Malay Archipelago are the big producers of copra and coconut oil. Palm oil and palm-kernel oil come chiefly from Africa; soya-bean, rape-seed and peanut oils from China.

These oils may also be classified as edible or commercial. Divided in this manner, the commercial oils used for manufacturing some inedible product such as paint would be linseed, castor and rape-seed. The edible oils would include cottonseed, peanut, corn, sunflower, coconut, palm, palm-kernel and soya-bean. Some of the oils are in both classes.

There are three general methods of obtaining the edible oils—extraction, expeller pressing and hydraulic pressing, or combinations of these methods. The exact procedure varies according to the individual characteristics of the oil. In the case of peanut oil, the peanuts after being shelled, blanched and degermed are given a preliminary pressing in an expeller press, the product being a virgin oil which is capable of being used for edible purposes without further treatment. The cake from the expeller press is then ground, cooked and put through a hydraulic press to obtain the remaining oil.

For refining the crude oils, the method almost universally employed is to agitate the oil with a solution of caustic soda, allow the resulting soap to settle, and siphon off the supernatant oil. This procedure neutralizes the acid in the oil, coagulates the albuminous material and, in settling, drags down what meal or other foreign matter there may be in the oil. A certain amount of the original color is removed at the same time. After being siphoned off, this neutralized oil is clarified by further settling and is then mixed with some bleaching agent such as fullers earth or fitt-char and pumped through a filter press. The oil is then run into a deodorizer and blown with steam at a high temperature. For salad oils, a mild-flavored oil is refrigerated to separate stearine, which is then removed by filtration.

Modifications of the caustic refining treatment include the Chisholm process, in which sodium silicate is added to the caustic soda, and the Baskerville process, using cotton linters with the caustic, a percentage of soda ash being added before removing the foots in a filter press. The foots

BENZENE BUILDING

top of the light-oil stills in a vertical position. The superheaters are of the high, upright, cylindrical type. All light-oil and benzene vapor coolers and condensers are of the open coil with outside water spray type. They are located outdoors directly over the wash oil coolers of the same type, thus conserving water.

The crude and pure stills are each of 15,000 gal.

or settlings from the refining process consist of neutralized fatty acids, coagulated albuminous matter, dirt and other impurities, precipitated coloring matter, saponified oil, and unsaponified oil entrained in the foots. Formerly, foots were either pumped to a tank car or cut with sulphuric acid to form "black grease." In either case, their destination was the soapmaker. Recently it has been found that by diluting the foots with water and passing them through a Sharples supercentrifugal, a certain proportion of the entrained unsaponified oil can be recovered. This process is one of the most important improvements in the old method of refining that has been developed in recent years.

The hydrogenation process has also had a wonderful influence upon this industry. For one thing, it has made the soap manufacturer independent of the supply of harder fats, as he can buy softer oils and harden them according to his needs.

There are unlimited opportunities for research in this field. The action of fullers earth and caustic soda, the disagreeable flavors and odors in the oils, the exact mechanisms of the various reactions which take place—all these require careful study. Often an oil is received at the refinery which defies all efforts to obtain concordant results either in the laboratory or the factory, in spite of the greatest care in handling. There are apparently some variable factors which cannot be brought under control at present because they are not thoroughly understood.

Recent Chemical & Metallurgical Patents

American Patents

Complete specifications of any United States patent may be obtained by remitting 10c. to the Commissioner of Patents, Washington, D. C.

French Process Zinc Oxide.—In the production of French oxide by the retort volatilizing process it is the common practice in the art to charge the retorts with broken up slabs of zinc, which must be melted and brought to the volatilizing temperature before the oxide production can take place. The production of French oxide in this way is an intermittent operation, each charge being worked off before the next charge is introduced into the retort. As a result the retorts can be operated at their maximum capacity during only a part of the time. This intermittent method of operation requires frequent cleaning of the retorts, while the retorts themselves not infrequently crack

or fail and must be replaced, thus further decreasing the output of the furnace and increasing the labor and expense of operation. So also such intermittent operation of the retorts is wasteful of fuel for the reason that the retorts must be heated during the time interval between the end of one operation and the beginning of the next, as well as during the preliminary period of melting the zinc

and heating it to the required temperature, and also during the entire working-off operation, during the latter part of which the retort is operated at a greatly reduced capacity owing to the progressively decreasing amount of molten zinc remaining therein.

In order to make possible continuous operation JAMES A. SINGMASTER of Palmerton, Pa., proposes to maintain an approximately constant amount of zinc in each retort by adding molten zinc from time to time. For this purpose an auxiliary melting furnace is supplied with metal from the spelter furnaces. A later improvement by WALTER L. COURSEN is to cast the zinc in small rods, which are placed in the retorts at intervals. In either case the level of molten metal in the retorts is kept practically constant so that even when lead is present the retort may be operated for a long time before the concentration of lead becomes great enough to cause trouble. The accompanying illustration represents a vertical transverse section of a retort furnace. The retorts 2 (of which there are twenty in each furnace) have the usual dam 3 at one end and the usual opening 4 above it and are closed at the other end by a closure or luting 5, through which extends the pipe 6. The retorts are heated externally to a temperature above the volatilization point of zinc but below that of lead, iron, etc., and the retorts are kept filled with a reducing gas, such as clean producer gas, introduced through the pipe 6. The introduction of this gas prevents premature oxidation of the zinc vapor and also assists in sweeping out the zinc vapor as fast as formed. The zinc vapor and the producer gas combine with the oxygen of the air at the mouth of the retort, and the oxide thus produced is collected in the usual way. For use with the present inventions doors 7 are provided in the ends of the pipes 6. Through these the molten zinc or rods may be added to the retorts. (1,372,462 and 1,372,486; assigned to the New Jersey Zinc Co.; March 22, 1921.)

Apparatus for Indicating the Height of Liquids in Receptacles.—Referring to the figure, the gaging device comprises a weighing cylinder 4 supported in position adja-

cent the boiler 1 by suitable brackets 5 and 6, and a dash-pot 7. The weighing cylinder 4 is yieldingly mounted upon a calibrated spring 8 and has communication with the interior of the tank by means of the pipes 9 and 10, which are of sufficient length to extend around the tank to a point diametrically opposite the position of the weighing cylinder. The pipes 9 and 10 by reason of their length flex readily and avoid exerting any appreciable restraint against the free vertical movement of the weighing cylinder under conditions of operation. The calibrated spring 8 surrounds the weighing cylinder 4 and is interposed between the bracket 5, which is made fast to the exterior of the tank 1 and a flange 11 formed on the top cap of the cylinder 4, so that the weight of the cylinder and its contents will be carried by the spring, the whole exerting a compressive tension against the spring. Extending from a union 12, which affords communication between the pipe 9 and cylinder 4, is a guide rod 13 loosely fitting within the bracket 6, which is riveted or otherwise secured to the tank forming an aligning means which confines the movement of the weighing cylinder to the vertical.

It will be understood from the description thus far that the liquid supplied to the tank 1 will flow without restraint

through pipe 10 into the weighing cylinder 4 and will rise therein to an equal level, causing the weighing cylinder to descend against the tension of the calibrated spring 8. In order to indicate the level of the liquid entering the weighing cylinder 4, and hence the level of the liquid within the tank 1, the following instrumentalities are used. Upon the side of the weighing cylinder 4 is arranged a rack 14; co-operating with the rack is a pinion 15 mounted upon a shaft 16, the latter being guided by a bearing 17. This shaft has mounted upon its extremity an indicating hand 18, which co-operates with a dial 19, which is suitably graduated. It will be obvious that as the weighing cylinder 4 moves in either direction this motion is communicated to the hand 18, causing the latter to vary accordingly upon the dial. By suitably proportioning the parts such as increasing the size of the pinion 15 the extent of movement of the hand 18 over the dial can be governed.

The sensitiveness may be increased by the use of a counterweight which balances the weight of the cylinder. One means of accomplishing this result consists in using a link 27 pivoted to the weighing cylinder 4 at 28, to which link is connected a lever 29 pivotedly supported at 30. The opposite extremity of this lever is connected to a link 31 which supports a counterweight 32, having a projecting extremity 33 guided in a guide-bearing 34. (1,367,689; JOSEPH C. FULLER, of Sewaren, N. J.; Feb. 8, 1921.)

British Patents

Complete specifications of any British patent may be obtained by remitting 25c. to the Superintendent British Patent Office, Southampton Buildings, Chancery Lane, London, England.

Tungsten.—Tungsten powder is obtained from sodium or potassium tungstate or both by mixing the tungstate with a chloride, preferably ammonium chloride, and a reducing agent such as wood, charcoal, anthracite or sawdust, and heating the mixture in the form of briquets or otherwise to 1,000-1,500 deg. C.

for about fifteen hours. The product is either cooled out of contact with air or is quenched in water. Any soluble tungstates formed may be precipitated with lime and calcium chloride and the calcium tungstate added to a subsequent charge. The furnace shown comprises a casing *s* and a retort *v* arranged in sections and heated by burners *e*, the joints between the sections being provided with asbestos packing *f* and spring washers *g*. The upper sections *a*, *b*, *c* are mounted on a platform *w* and the bottom section *d* in bearings on a carriage *j*, tilting means *l* being provided. As the charge is heated, it melts and sinks into the section *d*, ammonia which is evolved escaping through an opening *o* and being recovered for re-use. The chamber *d* is then disconnected and removed and the heating completed under a separate hood. According to the provisional specification, fluorides may be used instead of or in addition to chlorides. (Br. Pat. 155,600, C. J. HEAD, London; Feb. 23, 1921.)

thioglycollic acid dissolved in caustic soda. By addition of alcohol, silver thioglycollate of sodium, $\text{AgS-CH}_2\text{-COONa}$, is precipitated as a yellow powder, which is soluble in water and is of value in treating gonococci diseases. (Br. Pat. 156,103; not yet accepted; CHEMISCHE FABRIK FLORA, Zurich, Switzerland. March 2, 1921.)

Assimilable Phosphates.—Phosphates are rendered assimilable as a manure by grinding them with a large quantity of water to which has preferably been added a small amount of acid or alkali. The finely divided phosphate becomes hydrated and assumes a colloidal-like form which after drying is equal in value to water-soluble phosphates. The addition of 0.1 to 3 per cent of sulphuric, nitric or phosphoric acid is sufficient to accelerate this transformation considerably. The process is facilitated by conducting it under pressure or by heating to about 90 to 95 deg. C., or by adding protective colloids such as tannin, salts of lysalbinic acid, or the alkali salts of humic acid. Bone-meal and guano may be subjected to the same process. In an example slag phosphate is first ground in a phosphate mill and is then disintegrated in the presence of six times its amount of water. The resulting suspension is weakly acidified with a gaseous or liquid acid and allowed to separate into two layers. The bottom layer of phosphate mud is withdrawn, filtered and dried; preferably by blowing with hot air or by heating with waste gases. (Br. Pat. 154,124; not yet accepted; H. PLAUSON, Hamburg, and J. A. VIELLE, Westminster. March 2, 1921.)

Zinc Sulphide—Lithopone.—Zinc polysulphide is obtained by precipitation of a zinc salt of an organic or inorganic acid such as zinc chloride with an alkali or alkaline earth polysulphide such as a barium polysulphide, while maintaining an excess of the zinc salt. The zinc chloride may be obtained by treating zinc sulphate with barium chloride, and the barium sulphate is reduced to sulphide, dissolved, and converted into any polysulphide by treatment with the requisite quantity of sulphur. Lithopone is obtained by precipitating zinc sulphate with barium polysulphide in presence of a soluble zinc salt or other than the sulphate. The precipitated zinc polysulphide is completely washed and dried and is heated first at about 300 deg. C. until any oxide present is converted into sulphide, the sulphur dioxide being removed, and then to about 700 deg. C. The heating is effected in a clay crucible and a current of inert gas such as nitrogen may be passed through. The sulphur expelled may be collected and used for making more barium polysulphide. (Br. Pat. 155,824; not yet accepted; FABRIQUES DE PRODUITS CHIMIQUES DE THANN ET DE MULHOUSE, Thann, France. March 2, 1921.)

Nitrocellulose Compositions.—Nitrocellulose is dissolved in non-volatile liquid tricresyl esters of phosphoric or thiophosphoric acid, or in halogen substitution products of these esters. The solution, with the addition of fillers and coloring matter, may be combined with one or more layers of fabric to form driving belts, floor coverings, etc., or may be molded under pressure into various forms for insulating and other purposes. A typical composition contains 20 to 25 per cent nitrocellulose, 28 to 35 per cent phosphoric acid tricresyl ester, 15 to 20 per cent chalk or fossil earth, 2 to 5 per cent English red, and 35 to 15 per cent finely ground sawdust. (Br. Pat. 156,096; not yet accepted; C. CLAESSEN, Berlin, March 2, 1921.)

Acetic Acid.—In the catalytic oxidation of liquid acetaldehyde to acetic acid the formation of peracetic acid is inhibited by using as catalysts salts containing water of crystallization—e.g., hydrated salts, particularly the acetates, of nickel, cobalt, manganese, chromium or copper, alkali and alkaline earth hydrated salts, and alums. Salts specifically mentioned are ferrous sulphate, sodium acetate, potassium cobalt sulphate, potassium ferrisulphate and manganous sulphate. According to the example, oxygen or air is passed into acetaldehyde containing finely divided ferrous sulphate ($\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$), the resulting acetic acid separated from the salt and then distilled, preferably in vacuo. The remaining ferric sulphate can be used afresh after it has been reduced and crystallized. (Br. Pat. 156,146; not yet accepted; H. PLAUSON, Hamburg, and J. A. VIELLE, Westminster. March 2, 1921.)

Thioglycollates.—An aqueous solution of thioglycollic acid is treated successively with an aqueous solution of a silver salt and one of caustic soda; or the silver solution, for example silver nitrate or fluoride, may be added to the

Current Events

in the Chemical and Metallurgical Industries

Knox Dye Amendment Passes Senate

The Knox amendment continuing the control of the War Trade Board over imports of dyes was embodied in the emergency tariff bill in exactly the form as approved by the committee and the bill itself was passed May 11 by a vote of 63 to 28. The measure now goes to conference, where the differences between the Senate and House bills will be adjusted. It is practically certain that the House conferees will accept the Knox amendment. Senator Moses of New Hampshire, chief opponent of the amendment, declares that its adoption means that the licensing of dye imports not only will extend during the six months' life of the emergency tariff, but will be written into the permanent tariff bill as well.

SENATOR MOSES CONDEMNS THE MEASURE

Senator Moses condemned the whole emergency tariff measure as "unscientific, unjust and sure to defeat the hopes of those who have advocated it." Embargo and licensing systems were condemned by the New Hampshire Senator as being un-Republican, un-Democratic and un-American. He said the amendment "puts hundreds of business men to the disadvantage of exposing the secrets of their business to some petty agent of the War Trade Board, which continues to function, though war long since has ceased." He condemned the dye industries for spending large sums in pushing the amendment when they "were hammering at the gates of Congress with the plaintive cry that they could not live out the winter." In that connection Senator Moses went into some detail as to the expenditures which he alleges were made by the American Dyes Institute in its effort to secure this legislation. He declared that Morris R. Poucher "is the Dyes Institute, is the du Pont company, is the Textile Alliance and it is now proposed to make him the doorway to the War Trade Board."

"In these various capacities," continued Senator Moses, "the way will be paved to him to know not only the details of the business of every dye manufacturer in the United States, but to secure an accurate line on the consumer as well—to whom he may dictate what he may and may not use. The dye consumers of the country may as well understand in the beginning that the entire dyestuffs business of the United States is to be turned over to Mr. Poucher and to those whom he represents and that they will determine who shall or shall not continue in business, whether it be manufacturing, importing or consuming."

Senator Moses pointed out that the word "dyestuffs" is new so far as American statutes are concerned. Since the word has received no legal interpretation, he expects that it will be interpreted to include not only the coal-tar colors but the natural dyes, such as logwood, fustic, natural indigo, prussian blue and the like.

SENATOR KNOX REPLIES

Senator Knox, speaking on the floor of the Senate in defense of his amendment, declared that he had been amused by the arguments of Senator Moses, which he characterized as being prejudiced. "It is not my purpose," said Senator Knox, "to approach the consideration of the amendment from the standpoint of a profit and loss account of a Dolly Varden calico mill in New England, but from the standpoint of the roster of the dead of the great war." He stated that he would omit from his arguments the economic reasons for protecting the dye industry and would confine himself solely to the need for establishing a great chemical industry because of its importance for the national defense.

When the war began gas shells constituted an insignificant proportion of projectiles, Senator Knox pointed out, yet at the time of the Germans' last retreat it was found

that fully 50 per cent of their projectiles were filled with gas rather than with high explosives. He quoted extensively from General Fries to bring out the importance of chemical warfare and the certainty that it will be employed in any future conflicts. He also embodied in his remarks certain observations of Colonel Phillippe Bunau-Varilla in speaking of the pre-war blindness of the French people in not meeting the German advance in organic chemistry, so as to be able to cope with them in the production of chemical armament.

Senator Knox had printed in the *Congressional Record*, as an adjunct to his speech, practically the entire address delivered by General Fries at the recent Chemical Warfare Service annual dinner. He also included, as a part of his remarks, a memorandum written by General Fries to General Leonard Wood in which was pointed out how easy it would be for Japan, in the event of war with that country, to take the Philippines with the aid of gas.

In the course of his remarks, Senator Knox called attention to the fact that in 1914 there were seven manufacturers of dyes in the United States. In 1920 there were 184 dye manufacturers in this country, which fact he used as an argument to show that the industry is not being monopolized by a few. He explained that necessarily some of these institutions must be great and must be enormously capitalized, since "when great things are being done in the world, it requires great instrumentalities to accomplish them."

General Staff College Hears of Chemical Warfare

That the General Staff of the Army is coming to regard chemical warfare with greater sympathy may be judged by the fact that General Amos A. Fries on May 11 appeared before the General Staff College and delivered an exhaustive address on the underlying fundamental principles of chemical warfare. General Fries' remarks covered thirty-one typewritten pages. In the course of his address he declared that chemical warfare is the most scientific of all methods of fighting and is the most universally applicable of all the methods of making war. The use of gas, he said, is just as fundamental as was the introduction of gunpowder.

"The World War opened the eyes of England, France and Japan, as well as those of the United States," said General Fries in the course of his address. "Each of them today is struggling to build up a great chemical industry as the very foundation of successful war." At another point in his speech General Fries said:

"A part of the strategy of peace is the card indexing of the man power of a nation divided into special groups. In one great group must come those who have a knowledge of chemistry and the chemical industries. That must be so worked out that if war should come on a moment's notice, within twenty-four hours thereafter every chemist could be given his job, jobs extending from the firing line to the research laboratory. And that is the task of the Chemical Warfare Service."

General Fries reiterated a point he frequently has made that there never has been a case in history where a powerful weapon ever has been abandoned once its effectiveness had been proved. For that reason, he said, "our Government today is giving most serious heed to the need of building up a great chemical industry in the United States. We have the raw materials. We need only the factories and the trained men that go with them. We need of course, in addition to the development of the coal-tar industry, a production of heavy chemicals such as chlorine, sulphuric acid and the like, all of which, however, are bound together by community interest in peace as well as in war."

Engineering Council Urges Patent Office Relief

Wholesale resignations are crippling the United States Patent Office to the point of disorganization and are creating conditions that threaten American industrial enterprise and invention, it was declared in a statement issued by the American Engineering Council of the Federated American Engineering Societies.

The Council, through its patents committee, of which Edwin J. Prindle, of New York City, is chairman, asserted that the situation had become almost intolerable and quoted the new Commissioner of Patents, Thomas E. Robertson, as saying that remedial legislation at the present session of Congress is necessary if results approaching disruption were to be prevented.

The Council appealed for support of pending patent legislation, which provides sufficient increases in salaries to check the exodus of employees from the Patent Office to private employment. In a little over one year, it was stated, 110 of the force of examiners numbering 437 have resigned. During the first three weeks of the Harding administration six highly trained experts quit to accept salaries two or three times as great on the outside.

In the past year, according to figures furnished by Commissioner Robertson, 142 of the 560 clerical workers have left the service. There are thirty clerks in the Patent Office who receive only \$60 a month. They would get \$1,100 a year under the new salary bill.

The Council also made public a statement from Major A. M. Holcombe, former chief of the patent section, General Staff, United States Army, urging engineers to aid patent legislation and saying that patents play an increasingly important part in proportion to the degree of specialization in industry.

Chairman Prindle stated it was the unqualified opinion of the important engineering, research and manufacturing associations of the United States that the scientific and industrial interests of the country were being jeopardized by Patent Office conditions. The National Research Council, the American Chemical Society and the National Association of Manufacturers were cited by him as among the organizations favoring Patent Office relief.

"With our patent system working normally," he said, "many inventions will be produced each year which in the aggregate will add so much to the income of our country that the returns from income taxes will be much larger with the Patent Office properly supported. To deny the Patent Office relief is not economy, but waste. The European countries, taught by the war, are already strengthening their patent systems. America must not lag."

Extensions by Anaconda Company

Anaconda's annual report for the year 1920 contains the following information on new experimentation, construction and operation of new departments:

ANACONDA

Very little construction work was done at Anaconda during the year 1920, the principal items being the completion of the 50-ton phosphate plant, which was begun in the latter part of 1919, and the completion of the arsenic refining plant, work on which was begun at the same time. Both of these plants were operated in a very satisfactory manner.

The 50-ton phosphate plant treated approximately 1,500 tons per month of rock and produced about 900 tons per month of treble superphosphate, containing about 47 per cent available phosphoric acid. This plant is a pilot plant intended for developing the process of producing high-grade phosphate and demonstrating the marketability of the product. Plans are under way for the construction of a large commercial plant to treat 400 to 450 tons of rock per day, together with the necessary sulphuric acid plant.

The new arsenic-refining plant, the remodeling of which was completed during the year, contains two refining furnaces each capable of producing about 200 tons per month of refined arsenic. Toward the end of the year a baghouse was constructed to recover the fume from the gases leaving the arsenic plant. The entire system operated in a most satisfactory manner.

A small experimental plant for the production of liquid sulphur dioxide and an experimental precipitator for the precipitation of copper from sulphate solutions by means of liquid sulphur dioxide were completed and successfully operated during the year.

GREAT FALLS

A very considerable advance was made during the year in connection with the treatment of zinc plant residue and baghouse fume, by making the fume and the residue into briquets and smelting the same in one of the old copper blast furnaces, which was remodeled for this purpose.

At the rolling mill a double six-die wire drawing machine, a nine-die wire drawing machine and a seven-wire strander were added to the plant.

At the ferromanganese plant considerable work was done during the year in the way of reconstructing the furnaces as they wore out. Two of the furnaces were rebuilt along new and improved lines and the electrode holders were very much improved. The plant for the last half of the year operated very satisfactorily, but as there was a decided falling off in the demand for ferromanganese in the middle of December the operation of the Great Falls plant was discontinued.

EAST CHICAGO

The electrolytic white lead plant of the Anaconda Lead Products Co., located at East Chicago, Ind., was put in operation on Jan. 25, 1920, and immediately, as is usually the case in new process work, weaknesses in equipment and plant design developed, which from time to time were remedied and will be completely overcome in the near future. The cellroom of the plant developed a greater tonnage than was expected, thereby throwing out of balance the filtering, drying and barreling departments.

The process operated satisfactorily, the grade of the product being excellent, establishing a new standard of whiteness for white lead. Construction and operation of the plant were seriously hampered by a scarcity of labor, which was remedied only toward the close of the year. The plant made an output of eighteen tons of white lead per day during the last month of the year.

POTRERILLOS

The experimental mill of the Andes Copper Mining Co. at Potrerillos was started Jan. 25, 1920. Various alterations were made to permit of thorough tests on the oxide ores by a leaching process, to be followed by sulphur dioxide precipitation and iron cementation. The leaching experiments carried on during the year indicated a consistent extraction of 92 per cent of the copper content in the oxide ores treated.

The sulphur dioxide plant has been shipped to South America and should be in operation early in the year 1921. In the meantime tests on similar ores have been made at Anaconda, Mont. These experiments have fully corroborated the results obtained originally in the 1-ton plant at Anaconda and warrant the expectation of a very satisfactory recovery from the ores treated.

Due to shortage of fuel, the mill was shut down in September, 1920, but will be started up early in the year 1921.

Mme. Curie to Visit Washington

Mme. Curie arrived in New York City on the Olympic May 11 and was entertained at luncheon by New York chemists on May 17. She plans to visit Washington, where, on the afternoon of May 20, President Harding will present her with a gram of radium which has been purchased as a gift to her by the women of the United States. On the same evening a meeting in her honor will be held at the National Museum, where Prof. R. A. Millikan will speak on the subject of "Radium." The following two days will be spent in visits and entertainment in Washington, including dinners in honor of Mme. Curie at the French Embassy and Polish Legation, a trip to Mount Vernon, attendance at the formal opening of the cryogenic laboratories of the Bureau of Mines and a visit to the Bureau of Standards.

Annual Meeting, Society of Chemical Industry

The following message from Sir William J. Pope, president of the Society of Chemical Industry, was published in the April 15 issue of the *Journal* of the society:

As has already been announced, the next annual meeting of the Society of Chemical Industry will be held in Canada, in response to a very hearty invitation extended by the Montreal Section; the formal meeting extends from Aug. 29 to 31, but our Canadian friends have expressed the wish that the party from Europe will arrive a few days earlier so that they may be shown some parts of Canada not included in the extensive official program now being compiled. It will thus be convenient if as many of the visitors as possible will travel with me by the Melita, which leaves Liverpool on Friday, Aug. 12, and arrives at Montreal on or after Aug. 22.

At the close of the business meeting on Aug. 31, the members will leave Montreal by a special train for a four days' triangular tour of eastern Canada, during which visits will be paid to the paper and pulp works at Grand Mere, the largest in Canada, to the carbide and synthetic acetic acid factories at Shawinigan, and possibly to the aluminum and magnesium electrolytic plants. Sept. 2 will be spent at Ottawa and the next two days at Toronto. A boat trip across the lake has been arranged in connection with a visit to Niagara and to the chemical works and fruit farms on the Canadian side of the river. Sept. 6 will be spent in an inspection of the electrochemical works on the American side of the Niagara Falls, and the party will then proceed by train to New York.

From Sept. 7 to 10 the party will co-operate in a joint meeting of the Society of Chemical Industry and its American Section and the American Chemical Society; it will visit the great Chemical Exposition which opens at New York on Sept. 12, and which will certainly be one of the most important exhibitions of the chemical industry which has ever been held.

During the critical period through which all branches of the chemical industry are at present passing, when old markets are falling away and must be replaced by new ones, it is more than ever essential that British industrial chemists should seize every opportunity of gaining acquaintance with the conditions which prevail in the British Dominions and abroad; only by personal visits and by the establishment of new friendships and fresh business relationships can our members hope to be able to raise our chemical industries to the position indicated for them by the history and the geographical environment of these islands. Our Canadian and American friends have intimated their desire to furnish uncommonly extensive facilities for the inspection of works concerned with every branch of chemical industry, and it is certain that similar facilities cannot be granted to private individuals traveling alone apart from an official party such as is now being formed. The Council therefore desires to urge the members of our society to make every effort to accept the generous invitation extended to us by our transatlantic friends; we are convinced that the maximum benefit to our society and to the chemical industries of Great Britain, of Canada and of the United States can only be derived by the attendance of a large British party at the coming annual meeting.

New Chemistry Building at Buffalo

The Greater University of Buffalo, Buffalo, N. Y., will soon break ground for the construction of its proposed new chemistry building on Main St., contract for which was awarded recently to the J. W. Cowper Co., Fidelity Building. The structure will be three-story and basement, of Colonial style architecture; the facade will be of Indiana limestone with smooth light buff trim. The building will be constructed in the form of an H, with wings at the north and south ends, facing the campus.

A complete metallurgical laboratory will be located in the basement, supplemented by a dental metallurgical laboratory and electrochemical laboratory. The lobby on the main entrance floor will be used as a museum; in the north wing on this floor will be an organic laboratory, 48 x 96 ft., while the south wing will be used as a reading room, library and recitation room; at the front of the building on this floor will be the offices for the professors, smaller labora-

tories and supply rooms. On the second floor, the north wing will be used as an organic chemistry laboratory, and the south wing arranged for a microscopic laboratory, recitation room and lecture hall. Three large class rooms will also be located on this floor. The north wing on the third floor will be given over to a post-graduate laboratory and quantitative laboratory; in the south wing two other laboratories will be situated. The front of the building on this floor will be used for an analytical laboratory, with adjoining water and gas analysis laboratories and electrolysis department.

The building will have a total of approximately 17,000 sq.ft. on each floor, and has been designed to accommodate about 1,200 students. It is estimated to cost about \$400,000.

Development Work of the Bureau of Chemistry

The office of Development Work has recently been created in the Bureau of Chemistry of the United States Department of Agriculture to assist in the industrialization and commercialization of chemical processes and discoveries worked out in the laboratories of the bureau. The engineers in this branch will endeavor to design mechanical equipment to place the processes on a plant production basis and determine the manufacturing cost and market value of the products. The chemical discoveries relate to the utilization of waste agricultural materials for new purposes and to the deriving of new substances from farm products. One of the projects undertaken has been the production of sirup from sweet potatoes. The process as worked out in the laboratory has been very satisfactory and the engineers in the Development Division are now endeavoring to obtain data to assist in the establishing of a sweet potato sirup production industry if the scheme is commercially feasible.

Another project to be undertaken in the near future has to do with deriving furfural, cellulose flour and two grades of adhesive from corn cobs. Other lines of work following up closely the methods determined in the laboratory will be undertaken. The industrial contact for the bureau will be handled through this new division and the engineers will be called upon to maintain satisfactory industrial relations with the business interests of the United States.

In connection with this development work the United States Civil Service Commission will receive applications until June 21 for positions of associate development engineer at salaries from \$2,500 to \$3,600 a year, assistant development engineer at salaries from \$1,800 to \$2,500 a year, and junior development engineer at salaries from \$1,440 to \$1,800 a year. Appointees at annual compensation of \$2,500 or less, whose services are satisfactory, will be allowed the increase granted by Congress of \$20 a month.

Applicants will not be required to report at any place for examination, but will be rated upon their education, training, and experience, as shown by their own statements and by corroborative evidence, and upon published writings or theses submitted with their applications. They must qualify in at least one of eleven specified engineering branches.

The requirements for entrance to these examinations and other information in full, together with application blanks, may be obtained by communicating with the United States Civil Service Commission, Washington, D. C., or the secretary of the local board of United States civil service examiners at the post office or custom house in any city.

C.W.S. to Test Gas Bombs in Naval Aerial Warfare

In connection with the tests of aerial bombs to be conducted off the Atlantic coast June 21 the Chemical Warfare Service is planning to experiment on the effectiveness of poison gas bombs. Non-explosive bombs filled with brombenzylcyanide will be dropped on a ship carrying a crew provided with gas masks. It has been pointed out that the ventilating system of all warships is based on a suction system drawing air through tubes to every part of the vessel. This system would be the chief ally of an enemy gas attack, sucking the deadly gases into every nook and corner of the vessel.

New Jersey Chemical Society Meeting

In an address on "Scientific Preparedness," delivered before the New Jersey Chemical Society May 9, Prof. Marston Taylor Bogert pointed out the profound influence which the use of poison gas was bound to have upon the methods of conducting future wars. Since chemical warfare can be waged with materials prepared from such seemingly innocent sources as the chlorine obtained from salt brines, coke, ethyl alcohol from the fermentation of carbohydrates, and the nitrogen of the air, the problem of chemical disarmament is by no means a simple one. Considered from the defensive point of view the safest policy would seem to be one involving unceasing research and study on the methods of chemical warfare and the assurance of a permanent domestic dye industry through appropriate legislation.

At the conclusion of Prof. Bogert's speech a short business meeting was held. A resolution was adopted urging the passage of the emergency tariff measure with the Knox amendment covering dyes and chemicals. Dr. F. W. Zons reported that the final touches were being put on the Year Book. Arrangements have been made by the committee on chemical industry for a visit to the Procter & Gamble plant at Port Ivory, Staten Island, on Saturday, May 21. Members expecting to attend were requested by Dr. Traub to be at the Elizabethport-Staten Island ferry not later than 9:30 a.m. Following the election of new members C. L. Bryden announced that the society now had 704 members.

NICKEL

The technical program was continued by John F. Thompson, of the technical department, International Nickel Co. He outlined briefly the chemical and physical properties and uses of nickel and its more important alloys, such as Monel metal. A consideration of the applications of nickel compounds, however, brings out the interesting fact that with the exception of electroplating the demand is very slight. The property of forming two sets of compounds having valences of 2 and 3 respectively is utilized in one form of storage battery and some processes for the manufacture of nickel catalyzers depend upon nickel compounds. Research directed toward widening the field of application of these compounds has developed some interesting points. One of the most promising seems to be the use of nickelic hydroxide as a pigment for printing ink. It has an excellent bluish undertone and makes an ink which prints well. Furthermore, it can be bleached easily so that the recovery of newsprint is facilitated.

R. L. Suhl, also of the International Nickel Co., commented on the prevalent idea that the price of nickel compounds is too high to warrant use as indicated. He said that the price was due largely to the small output and that with increased demand the economies of larger production would result in a substantial lowering of the price.

Executive Committee of T.A.P.P.I. Holds Meeting

The first meeting held by the executive committee of the Technical Association of the Pulp and Paper Industry since the election of George E. Williamson as president took place at the Strathmore Inn, Woronoco, Mass., on Thursday, May 5, and lasted over Friday. There was a full attendance of members.

MUCH CONSTRUCTIVE WORK TRANSACTED

It is safe to say that at no previous meeting of the executive committee of T.A.P.P.I. has so much work of a constructive character been transacted. Plans of a service committee for the conduct of group meetings of the association were adopted and arrangements made for the fall meeting of the association to be held under the joint direction of T.A.P.P.I. and the American Pulp and Paper Mill Superintendents' Association at Washington, D. C.; York and York Haven, Pa., and Philadelphia, Oct. 18, 19 and 20, 1921. Fred A. Curtis, of the Paper Section, U. S. Bureau of Standards, Washington, was named general manager of the meeting for T.A.P.P.I. and he will be assisted by Grellet N. Collins, of Philadelphia, and others. Owing

to an expected attendance of upward of 500 members and an already extended program of mill visitations, etc., it was found necessary to curtail the entertainment features to some extent. It was arranged that trips to York, York Haven and Wilmington be made optional for Wednesday, Oct. 19. This curtails the session in Washington to one day, Tuesday, Oct. 18, but members could arrange to reach Washington on Monday, Oct. 17, and spend the day in seeing the sights of the capital.

NEW STANDING COMMITTEES NAMED

Other business transacted by the executive committee included the appointment of standing committees of the association for the ensuing year, the adoption of a budget and passing on estimates of income and expenditures. On a request by the Cost Association of the Paper Industry for an investigation of depreciation in values of machinery and apparatus a special committee of the association will be named for the purpose.

ELECTION OF MEMBERS

New members have been admitted by the executive committee during and since the annual meeting as follows: Charles L. Cockroft, night foreman, Everett Pulp & Paper Co., Lowell, Wash.; Richard H. DeMott, manager, industrial development department, SKF Industries, 165 Broadway, New York; Robert S. Finney, secretary and general manager, McNamee Kaolin Co., 60 Broadway, New York; Charles L. Harpham, manager of manufacturing, F. C. Huyck & Sons, Albany, N. Y.; Harry M. Hooker, sales manager, Hooker Electrochemical Co., 25 Pine St., New York; Benjamin K. Hotchkiss, sales department, Hooker Electrochemical Co., 25 Pine St., New York; Harold G. Ingraham, construction engineer, Marathon Paper Mills Co., Rothschild, Wis.; Dr. Edwin A. Rees, chemist, F. C. Huyck & Sons, Albany, N. Y.; John O. Ross, president and general manager, J. O. Ross Engineering Corporation, 30 East Forty-second St., New York.

GENEROUS CONTRIBUTION TO VOCATIONAL EDUCATION FUND

A generous contribution to the funds of the Vocational Education Committee is announced, the Champion Fibre Co., Canton, N. C., having recently sent in its check for \$500. This sum comes at a time when it is greatly needed for the completion of the work undertaken by the Joint Vocational Education Committee of the Pulp and Paper Industry of the United States and Canada, and it is hoped that the good example of the Champion Fibre Co. will be followed by other firms that have not been previously heard from.

Chemical Club of Philadelphia After More Members

The Chemical Club of Philadelphia is arranging a campaign for increased membership. At present there are more than fifty members, representing about thirty chemical companies in the city. Recently elected officers for the coming year are: J. H. Stutt, du Pont Co., president; F. S. Havens, Atlantic Products Corp., vice-president; W. J. Thorn, Innis, Speiden & Co., treasurer; W. H. Davis, Harshaw, Fuller & Goodwin Co., secretary.

Obituary

C. H. CLARKE, president of the Clarke Chemical Co., Denver, Col., died recently at his home in that city.

AMBROSE MONELL, president of the International Nickel Co. for fifteen years and a metallurgist of note, died on May 2 at Beacon, N. Y., where he was undergoing a rest cure in an endeavor to recover from nervous prostration which had endured for several months. He leaves a widow, two sons and two daughters. Mr. Monell was born in New York City in 1874, and was graduated from the School of Mines, Columbia University, in 1896. He was then metallurgical engineer and assistant to the president, Carnegie

Steel Co., during which time he patented the steel process which bears his name. His idea was to adapt the Talbot continuous open-hearth process to a stationary furnace without retaining a heavy bath of molten metal at all times. As now practiced by the Carnegie Steel Co., molten pig iron is poured into a furnace containing white hot scrap, whereupon the impurities are rapidly oxidized and join with the lime and ore on the furnace bottom. Most of the slag boils out a special slag notch, or is skimmed off. What is known as the "lime boil" lasts two or three hours longer. After an hour more for adjusting the carbon content the steel is tapped. As head of the International Nickel Co., Mr. Monell was signally successful. His name has become widely known by the exploitation of Monel metal, an excellent natural alloy produced directly from the company's Canadian ore. These sulphide ores are roasted, and smelted into matte, a mixture of copper, nickel and iron sulphides. The iron sulphide is then eliminated by blowing the molten matte in a bessemer converter, and the resulting copper-nickel sulphide reduced with charcoal. When America entered the World War, Mr. Monell was commissioned Colonel in the aviation service and immediately went to France to organize the flying service on that side. He commanded at one time the day and night bombing groups. As a result of the intense strain under which he labored, his health broke down, never to be recovered.

Personal

A. J. BARNEBL, JR., formerly with the Dorr Co., is chief mechanical engineer for the K. B. Pulverizer Co., New York City, which is designing equipment for pulverizing coal.

L. H. CHAMBERLAIN has been appointed Western sales engineer for the Schutte & Koerting Co., with offices at 72 New Montgomery St., San Francisco.

B. DUNGLINSON, chemical engineer of the American Chemical & Sugar Machinery Co., has transferred his activities from the Philadelphia district to the Chicago office, with headquarters at 1725 Transportation Building.

AARON FRIEDMAN, formerly with Cooper & Cooper, Inc., is now with the New Process Metals Corporation of Newark, N. J. He will erect and superintend a plant for the manufacture of metallic cerium and other rare-earth metals.

O. H. KOCH, one of the members of American Engineering Council's executive board, has just completed visits to member societies in New Orleans, Birmingham and Nashville. He reports that they are much interested in the activities of the Federated American Engineering Societies.

E. C. LANE, chemist at the San Francisco laboratory of the U. S. Bureau of Mines, has left for an extended Eastern trip. He will spend several months in the Mid-Continent and Eastern oil fields and visit the stations of the bureau at Bartlesville and Pittsburgh, and also the Washington office, returning to San Francisco during the summer.

C. W. MILLER, president of the Davison Chemical Co., Baltimore, Md., has returned from a trip to the pyrites properties of the company in the West Indies.

L. W. WALLACE, the executive secretary of the Federated American Engineering Societies, has returned to his office in Washington after a visit to Milwaukee, Detroit and Chicago. At Milwaukee he addressed the Society of Industrial Engineers on industrial leadership. At Detroit he spoke at the annual banquet of the local engineering societies. In Chicago he attended the meeting of American Engineering Council's committee dealing with the licensing of engineers. This committee, in view of recent legislation, has made certain changes in its model bill. These changes will be laid before the executive board of the Council at its June meeting.

A. B. WILSON has resumed his former position as metallographer with the Titanium Alloy Manufacturing Co. and is engaged in work in connection with the use of ferro-carbon-titanium in steel.

Current Market Reports

The Chemical and Allied Industrial Markets

NEW YORK, May 16, 1921.

The heavy chemical market is strengthening up markedly, in spite of several declines in some items. Confidence throughout the trade is increasing after the long period of depression and it looks as though the pendulum is about to swing back. Business, however, is still far from normal, but the general attitude is much more hopeful, as steadiness is increasing throughout the general list. Even *caustic potash*, which has been consistently the weakest commodity in the market, is showing signs of firmness. The stand taken by leading manufacturers of the country's big basic products in reference to labor is a sign of decreased inflation of producing costs and assures healthier markets a little later in the year. The announcement of a lowering of discount rates by Federal Reserve banks in various parts of the country is significant that frozen credits are being thawed out. This is one of the brightest features that has confronted industry since the beginning of the year. It is also apparent that a reduction in freight rates will shortly be made and, altogether, developments are working toward a satisfactory end from a business point of view.

GENERAL CHEMICALS

Importations of foreign chemicals and the desire of foreign interests to compete in the American market are features of great concern to American producers. Higher prices were named for imported *nitrite of soda* and the market closed in a firm condition with the passage of the emergency tariff bill. This undoubtedly will prevent the keen state of competition which has existed between domestic and imported nitrite. Prices are decidedly firm on resale *caustic potash*, with the imported material, 88-92 per cent, offered at 6c. per lb. Consumers are taking a moderate amount of this material at the low prices and it is understood that the soap trade has taken large quantities. Prominent dealers offered *acetate of soda* for immediate shipment on the basis of 4½c. per lb. f.o.b. works. It is intimated that the figure might be shaded on a firm bid for a round lot. The present movement is quiet and small lot operations feature the market. Resale stock of *bichromate of soda* was quoted at 8c. per lb. in several directions ex-store N. Y., and while odd lots can still be purchased at 7½c., it is doubtful if very much business could be placed below the outside figure. Inquiries are said to be confined mostly to 5 and 10 lot quantities. Second-hand prices on *caustic soda* are reported at \$3.60@3.65 per 100 lb. ex-warehouse and \$3.75 f.a.s. steamer. The inquiry is irregular, with small lots attracting the most attention. Producers state they are placing a fair amount of business with the consuming trades and quoted the former range of 3½@3¼c. per lb., basis 60 per cent, f.o.b. works. Higher prices for *nitrite of soda* were named on spot and the market covered a range from 6½@7c. per lb. The advance was not accompanied by any radical activity. Consumers are taking small lots on the advance but did not appear eager to extend commitments. Imported *prussiate of soda* is showing strength in the open market and most sellers are not inclined to shade 12½c., while 13c. was named in several quarters. Offerings were not heavy but seemed sufficient to meet the current extent of inquiries. Occasional sales of light *soda ash* in bags went through at \$2.10 per 100 lb. Barrels were held at \$2.40@2.50 ex-store N. Y. The scarcity of offerings is keeping the market in a firm position. Producers report sales at \$1.62½@1.72½, basis 48 per cent, f.o.b. works in single bags. *Dense ash* is held at 10c. per 100 lb. premium. An arrival of a few 100-ton lots of ash was noted from Liverpool. Sellers of the imported material asserted that all April shipments were made and that May delivery is moving steadily.

Spot sales of *formaldehyde* were reported at 14½c. per lb. by second hands. Quotations are heard from 14@15c. per lb. according to seller. Buyers are taking moderate quantities of this chemical for miscellaneous consuming requirements. The undertone of the *glycerine* market rules steady regardless of the small volume of trading. Sellers' views on the dynamite are 15@15½c. per lb., while c.p. glycerine was held at 17@17½c. The *alcohol* market is still in a disturbing state and competition is keeping prices soft. Supplies of *ethyl alcohol* are easy and prices range from \$4.65@ \$5.25 per gal., according to quantity. Small lots of *denatured* moved in moderate volume and sellers are asking from 32@48c. per gal., depending on quantity and formula. There has been little change in *methanol* prices, which range from 75c.@\$1.15 per gal., depending on grade. Factors in *fluoride of soda* report sales at former levels, with small lot sales continuing to feature the market. Quotations range from 12@13c. per lb. The market on *bleaching powder* is very unsettled in the absence of any marked demand and prices among resellers are very hard to place. Offerings f.o.b. works from second hands have been heard all the way down to \$2.15 per 100 lb. Makers' quotations are given as \$2.75 per 100 lb., but this figure has little meaning in the present market. Makers of *lead acetate* have kept their prices at former levels and are quoting the white crystals at 13@13½c. per lb. and the brown variety at 11½@12½c. per lb. Producers of gray *sal ammoniac* have reduced their prices and are now quoting on a parity with the imported material at 7½@8½c. per lb. Imported white granular is quoted at 6½@7½c. per lb. American makers of white *sal ammoniac* are holding at 10@10½c. per lb.

COAL-TAR PRODUCTS

On Wednesday, May 11, the Senate passed the emergency tariff and anti-dumping bill, retaining all amendments recommended by the Finance Committee, but rejecting those individually proposed. The vote was 63 to 28. It is expected to become law practically unchanged. There is no doubt now among leading interests that the long period of uncertainty that has been such a drawback to the coal-tar industry will automatically pass with the enforcement of this new legislation. The volume of trading during the past week was of little larger proportion and the inquiry in one quarter and another was reported as more active. Full-time operation is noted in several mills where the four days a week schedule has been in force since last November. The lower bank rate is accepted as a good sign and if efforts now being made to secure financial assistance from the banking authorities are at all successful, a steady improvement in foreign business is expected. Dyestuffs have been more actively traded in during the period and principal factors are firm in their views on prices. Swiss and German dyes have been arriving quite regularly and occasionally small lots are available in resale quarters. Intermediates have held quite steady with a few moving more actively, while some of the less important have shown little evidence of any improvement.

Reports from some quarters on *para-amidophenol* reflect an improving demand, although there is little in the line of buying for future needs. Supplies are readily available and prices steady with the base at \$1.60@ \$1.70 per lb., and the HCl at \$1.75@ \$1.80 per lb. *Aniline oil* varies according to seller, ranging from 20@25c. per lb. It is possible to do 32c. per lb. on *beta naphthol*, although producers' figures are 42@45c. *Dimethylaniline* is quiet and only small quantities are called for with prices at 42@55c. per lb., depending on seller and quantity. Supplies of *diphenylamine* are easy, but prices are steady at 60@70c. per lb., with trading in fair volume. The consuming demand for *metaphenylenediamine* is fairly good and prices are steady at \$1.15@ \$1.25 per lb. Factors in most quarters report a regular supply of *toluidine* available while the demand is limited to small routine movement with prices ranging from \$1.25@ \$1.35 per lb. Trading in *toluene* was shown only in small lots during the week. There has been no change in the price level at 28@31c. per gal., depending on quantity, although second hands might shade down to 27c. on firm business. The market for *xylene* shows little change from

day to day, with a slight routine consuming demand. Supplies of the pure are quoted at 40@45c. per gal.

VEGETABLE OILS

Trading in *cottonseed oil* lacked snap and the undertone was rather heavy considering the favorable turn of events in Europe. Grains, provisions and cotton moved upward, but this caused hardly a ripple in the cottonseed oil trade. Export inquiry was dull, with domestic demand also quiet. The crude material was a shade easier at the mill, sales passing at \$5@ \$5.05 per 100 lb. The inquiry for *linseed oil* was reported as fair, consumers showing some interest in both nearby and July-September contracts. The undertone was firmer and while crushers no longer offered raw oil for nearby delivery at 64c. per gal., it was intimated that firm bids might still be accepted on carlot orders. Crushers were asking from 65@67c. per gal. for May-June shipment, with July-August oil commanding 66@68c., according to sellers. The market for *chinawood oil* closed higher at 12@12½c. per lb. in barrels, spot delivery. May shipment oil was held at 10¼@11c., with June quoted at 10½c. per lb. The Coast market for prompt shipment oil was quite strong at 11c. asked. Demand for *coconut oil* was less active, bids being below the market and no important sales going through. On the Coast Manila oil for May shipment was offered at 8½c. per lb., sellers' tanks, although some holders were still asking 8¾c. Copra inquiry was fairly active, but the asking price was considered too high. Bids were noted for Ceylon copra at 5½c. and Manila at 5c. per lb., c.i.f. N. Y. Crude *corn oil* in Chicago was firm, closing at 5½c. per lb. sellers' tanks, nearby delivery. Southern mills were asking from 6@6½c. per lb. for domestic crude *peanut oil* in buyers' tanks. The demand was quiet. Oriental oil was held at 6¼c., sellers' tanks, f.o.b. Coast.

WAXES

Offerings of *carnauba wax* were fairly liberal and with the primary markets unsettled, prices here were barely steady at the recently reduced rates. Demand was quiet throughout the week. *Flor* was held at 60c. per lb., with the No. 1 at 58@59c. On the lower grades there was scattered interest in futures, but spot quotations were generally maintained at 17@17½c. per lb. for the No. 3 North Country. The crude oil situation had little or no effect upon the market for *paraffine wax*. Export demand covering forward contracts was comparatively quiet and with some selling pressure noted here prices were irregular. Domestic inquiry also was reported slow. Crude white scale wax, 122-124 deg. melting point, was offered in carlots at 2¼c. per lb. in some directions and 2½c. on firm business. Match wax closed at 3¼@4c. per lb. Refined paraffine, 118-120 deg. melting point, was offered at 3¼c. per lb., while 130-132 closed barely steady at 5@5½c. per lb.

The Iron and Steel Market

PITTSBURGH, May 13, 1921.

As indicated in last week's report, it has become clear that the iron and steel trade is in no better condition than a month ago, and the continued failure of any definite improvement to develop now suggests that on the whole the condition must be regarded as worse. The proverbially dull summer season being now not far distant, the prospect is slim for any real improvement to occur in the near future. For some time past the common prediction in steel trade circles has been that there would be no important improvement before September or October, and that prediction holds good, with the appendage that conditions are likely to be somewhat worse meanwhile.

Using some estimates in conjunction with the monthly report of the American Iron and Steel Institute showing the production of steel ingots in April of the companies that make monthly reports, it may be concluded that in April the independent steel producers in general operated at about 22 per cent of capacity, and this with an operation of about 41 per cent by the Steel Corporation makes an operation for the whole industry of about 31 per cent of the estimated capacity of 52,500,000 tons of ingots per annum. The independents had operated at about 30 per cent in January and February, rising to about 32 per cent in March. The

Steel Corporation's operations had declined from a 90 per cent rate in January, so that the two parties are now closer together.

There is no indication that operations have been any heavier in the past week than the average of April, there being rather room for the conclusion that there has been a slight decrease. The lead of the Steel Corporation over the independents seems likely to be maintained. While the corporation loses each month in its unfilled obligations—by 439,541 tons in the case of April—its constantly lowering rate of operation has made it that month by month the remaining unfilled tonnage would last a longer time. Thus at a 40 per cent operation the unfilled tonnage of 5,845,224 tons shown at the end of April would last a trifle over ten months. The independents have very little contract tonnage on books, as they had high prices last year and neither solicited nor were offered contracts for extended periods, so that they must now depend upon business picked up from time to time.

TEST OF STEEL PRICES

It is now a month since the steel market was equalized by the independents advancing their prices on most commodities and by the Steel Corporation reducing its prices. The new prices have been maintained to date, in a way, but it is the common remark that the prices have not been seriously tested as yet. It is predicted that the real test, whether the independents will all adhere to these prices, will come during the next thirty days; in other words, that if the prices last until the fore part of June they will hold through the summer. A new situation might be presented in the fall.

There are occasional reports of price irregularities, usually ascribable to a particularly attractive tonnage of business being offered. Thus an oil company is said to have been quoted \$3 a keg on 4,200 kegs of nails, the regular price being \$3.25, while the Ford Motor Co. is alleged to have bought all or a large part of a requirement of 4,000 tons of hot-rolled strips at 2.40c., the regular quotation being 2.75c. On ordinary lots of the various finished steel products there do not seem to be any cut prices being quoted at present.

While the steel market is regarded as being altogether stagnant it should be remembered that the industry has so grown that what was formerly a large tonnage is now a small tonnage relative to capacity. At the 31 per cent operation the steel industry appears to have shown for April there is represented about 250,000 net tons a week of the regular finished steel products, and that is really not a small tonnage for a hard times consumption, when the flow of steel into large construction work is very largely arrested. A 30 per cent operation today is equivalent to a 109 per cent operation of the capacity existing in 1903 or 1902, when the steel industry was regarded as being very large.

PIG IRON

The decline in pig iron prices continues, but at a relatively slow rate, there being only an occasional yielding, and then by a fraction of a dollar. When the market began to decline after reaching its peak at the end of last August the declines were recorded in steps of several dollars a ton at a time. On a 2,000-ton sale of basic pig iron by a merchant-furnace interest in the valleys \$22 furnace has just been done, this representing a reversion of the control to the merchant furnaces, sales for several weeks preceding having been by steel works interests, at \$22.50, the merchant furnaces holding aloof. Bessemer is offered at \$24 valley, as against the previous nominal quotation of \$25. Foundry iron is offered at \$23.50 valley, a decline of 50c. in the week. At these prices pig iron cannot have much farther to go, and as a matter of fact pig iron prices in general are a slightly greater percentage below their Industrial Board levels than are finished steel prices, although the great advance that has occurred in freight rates since the Industrial Board adjustment bears more heavily upon pig iron relatively than upon steel.

Connellsville furnace coke could probably be bought at \$3.25, a price that leaves little if any occasion for the consumers to demand a further liquidation.

General Chemicals

CURRENT WHOLESALE PRICES IN NEW YORK MARKET

Acetic anhydride.....	lb.		\$0.43	\$0.45	
Acetone.....	lb.	\$0.12	\$0.12	.13	.15

Strontium nitrate, powdered lb.	.15 - .15	.16 - .17
Sulphur chl ride, red lb.	.07 - .07	.07 - .08
Sulphur, crude ton	20.00 - 22.00	
Sulphur dioxide, liquid, cylinders extra lb.	.08 - .08	.09 - .10
Sulphur (sublimed), flour 100 lb.		2.25 - 3.10
Sulphur, roll (brimstone) 100 lb.		2.00 - 2.75
Tin bichloride, 50 per cent lb.	.18 - .19	
Tin oxide lb.		.40 - .42
Zinc carbonate, precipitate lb.	.16 - .18	.19 - .20
Zinc chloride, gran. lb.	.11 - .11	.11 - .12
Zinc cyanide lb.	.45 - .49	.50 - .60
Zinc dust lb.	.12 - .13	.13 - .14
Zinc oxide, XX lb.	.08 - .09	.09 - .10
Zinc sulphate lb.	.03 - .03	.04 - .05

Coal-Tar Products

NOTE—The following prices are for original packages in large quantities:

Alpha-naphthol, crude lb.	\$1.10 - \$1.15
Alpha-naphthol, refined lb.	1.25 - 1.30
Alpha-naphthylamine lb.	.35 - .40
Aniline oil, drums extra lb.	.20 - .25
Aniline salts lb.	.26 - .29
Anthracene, 80% in drums (100 lb.) lb.	.85 - 1.00
Benzaldehyde U.S.P. lb.	1.00 - 1.50
Benzidine, base lb.	.85 - .90
Benzidine sulphate lb.	.75 - .80
Benzoic acid, U.S.P. lb.	.65 - .70
Benzoate of soda, U.S.P. lb.	.65 - .70
Benzene, pure, water-white, in drums (100 gal.) gal.	.27 - .32
Benzene, 90%, in drums (100 gal.) gal.	.25 - .28
Benzyl chloride, 95-97%, refined lb.	.28 - .30
Benzyl chloride, tech. lb.	.20 - .25
Beta-naphthol benzoate lb.	3.50 - 4.00
Beta-naphthol, sublimed lb.	.70 - .75
Beta-naphthol, tech. lb.	.32 - .45
Beta-naphthylamine, sublimed lb.	2.00 - 2.25
Cresol, U. S. P., in drums (100 lb.) lb.	.16 - .18
Ortho-cresol, in drums (100 lb.) lb.	.25 - .27
Cresylic acid, 97-99%, straw color, in drums gal.	.70 - .80
Cresylic acid, 95-97%, dark, in drums gal.	.65 - .70
Cresylic acid, 50%, first quality, drums gal.	.45 - .50
Dichlorobenzene lb.	.07 - .08
Diethylaniline lb.	1.20 - 1.25
Dimethylaniline lb.	.42 - .55
Dinitrobenzene lb.	.30 - .32
Dinitrochlorobenzene lb.	.20 - .30
Dinitronaphthalene lb.	.30 - .40
Dinitrophenol lb.	.35 - .40
Dinitrotoluene lb.	.25 - .27
Dip oil, 25%, tar acids, ear lots, in drums gal.	.40 - .45
Diphenylamine lb.	.60 - .70
H-acid lb.	1.30 - 1.50
Meta-phenylenediamine lb.	1.15 - 1.20
Monoethylaniline lb.	.12 - .14
Monoethylaniline lb.	1.75 - 1.85
Naphthalene crushed, in bbls. (250 lb.) lb.	.08 - .08
Naphthalene, flake lb.	.08 - .09
Naphthalene, balls lb.	.09 - .10
Naphthalonic acid, crude lb.	.70 - .75
Nitrobenzene lb.	.12 - .15
Nitro-naphthalene lb.	.30 - .35
Nitro-toluene lb.	.16 - .18
Ortho-amidophenol lb.	3.15 - 3.40
Ortho-dichlor-benzene lb.	.15 - .20
Ortho-nitro-phenol lb.	.75 - .80
Ortho-nitro-toluene lb.	.17 - .20
Ortho-toluidine lb.	.20 - .25
Para-amidophenol, base lb.	1.60 - 1.70
Para-amidophenol, HCl lb.	1.75 - 1.80

Para-dichlorobenzene lb.	.15 - .20
Paranitroaniline lb.	.85 - 1.05
Para-nitrotoluene lb.	.85 - 1.00
Para-phenylenediamine lb.	1.95 - 2.00
Para-toluidine lb.	1.25 - 1.60
Phthalic anhydride lb.	.50 - .60
Phenol, U. S. P., drums (dest.), (240 lb.) lb.	.12 - .14
Pyridine gal.	2.00 - 3.50
Resorcinol, technical lb.	1.75 - 1.85
Resorcinol, pure lb.	2.25 - 2.30
Salicylic acid, tech., in bbls. (110 lb.) lb.	.21 - .23
Salicylic acid, U. S. P. lb.	.22 - .24
Salol lb.	.85 - .95
Solvent naphtha, water-white, in drums, 100 gal. gal.	.25 - .28
Solvent naphtha, crude, heavy, in drums, 100 gal. gal.	.14 - .16
Sulphanilic acid, crude lb.	.30 - .35
Tolidine lb.	1.25 - 1.35
Toluidine, mixed lb.	.40 - .45
Toluene, in tank cars gal.	.25 - .28
Toluene, in drums gal.	.28 - .31
Xylidines, drums, 100 gal. lb.	.40 - .45
Xylene, pure, in drums gal.	.40 - .45
Xylene, pure, in tank cars gal.	.45 - .45
Xylene, commercial, in drums, 100 gal. gal.	.33 - .35
Xylene, commercial, in tank cars gal.	.30 -

Waxes

Prices based on original packages in large quantities.

Beeswax, refined, dark lb.	\$0.23 - \$0.25
Beeswax, refined, light lb.	.25 - .27
Beeswax, white pure lb.	.45 - .47
Carnauba, Flora lb.	.60 - .61
Carnauba, No. 2, North Country lb.	.28 - .30
Carnauba, No. 3, North Country lb.	.17 - .17
Japan lb.	.18 - .18
Montan, crude lb.	.07 - .08
Paraffine waxes, crude match wax (white) 105-110 m.p. lb.	.03 - .04
Paraffine waxes, crude, scale 124-126 m.p. lb.	.03 - .04
Paraffine waxes, refined, 118-120 m.p. lb.	.03 - .04
Paraffine waxes, refined, 125 m.p. lb.	.04 - .04
Paraffine waxes, refined, 128-130 m.p. lb.	.04 - .05
Paraffine waxes, refined, 133-135 m.p. lb.	.06 - .06
Paraffine waxes, refined, 135-137 m.p. lb.	.06 - .06
Stearic acid, single pressed lb.	.09 - .09
Stearic acid, double pressed lb.	.10 - .10
Stearic acid, triple pressed lb.	.11 - .11

Naval Stores

All prices are f.o.b. New York unless otherwise stated, and are based on carload lots. The oils in 50-gal. bbls., gross weight, 500 lb.

Rosin B-D, bbl. 280 lb.	\$5.50 -
Rosin E-I 280 lb.	6.30 - 6.40
Rosin K-N 280 lb.	6.50 - 6.70
Rosin W. G.-W. W. 280 lb.	6.80 -
Wood rosin, bbl. 280 lb.	6.25 -
Spirits of turpentine gal.	.70 -
Wood turpentine, steam dist. gal.	.68 -
Wood turpentine, dest. dist. gal.	.66 -
Pine tar pitch, bbl. 200 lb.	 - 7.00
Tar, kiln burned, bbl. (500 lb.) bbl.	 - 12.50
Retort tar, bbl. 500 lb.	 - 12.50
Rosin oil, first run gal.	.40 -
Rosin oil, second run gal.	.44 -
Rosin oil, third run gal.	.47 -
Pine oil, steam dist., sp.gr. 0.930-0.940 gal.	 - \$1.80
Pine oil, pure, dest. dist. gal.	1.50 -
Pine tar oil, ref., sp.gr. 1.025-1.035 gal.	 - .46
Pine tar oil, crude, sp.gr. 1.025-1.035 tank cars f.o.b. Jacksonville, Fla. gal.	 - .35
Pine tar oil, double ref., sp.gr. 0.965-0.990 gal.	 - .75
Pine tar, ref., thin, sp.gr. 1.080-1.960 gal.	 - .35
Turpentine, crude, sp. gr. 0.900-0.970 gal.	 - 1.20
Hardwood oil, f.o.b. Mich., sp.gr. 0.960-0.990 gal.	 - .35
Pinewood creosote, ref. gal.	 - .52

Solvents

73-76 deg., steel bbls. (85 lb.) gal.	\$0.41 -
70-72 deg., steel bbls. (85 lb.) gal.	 - .39
68-70 deg., steel bbls. (85 lb.) gal.	 - .38
V. M. and P. naphtha, steel bbls. (85 lb.) gal.	 - .30

Crude Rubber

Para-Upriver fine lb.	\$0.17 - .17
Upriver coarse lb.	.11 - .12
Upriver caucho ball lb.	.14 - .14
Plantation—First latex crepe lb.	.18 - .17
Ribbed smoked sheets lb.	.16 -
Brown crepe, thin, clean lb.	.15 -
Amber crepe No. 1 lb.	.17 -

Oils

VEGETABLE

The following prices are f.o.b. New York for carload lots.

Castor oil, No. 3, in bbls. lb.	\$0.09 - \$0.09
Castor oil, AA, in bbls. lb.	.10 - .10
China wood oil, in bbls. (f.o.b. Pac. coast) lb.	.11 - .10
Cocanut oil, Ceylon grade, in bbls. lb.	.10 - .10
Cocanut oil, Cochon grade, in bbls. lb.	.11 - .11
Corn oil, crude, in bbls. lb.	.07 - .08
Cottonseed oil, crude (f. o. b. mill) lb.	.05 - .05
Cottonseed oil, summer yellow lb.	.07 -
Cottonseed oil, winter yellow lb.	.07 -
Linseed oil, raw, car lots (domestic) gal.	.65 - .66
Linseed oil, raw, tank cars (domestic) gal.	.58 -
Linseed oil, in 5-bbl lots (domestic) gal.	.68 - .69

Olive oil, Denatured.....	gal.	\$1.40	—	\$1.60
Palm, Lagos.....	lb.	.07½	—	.07½
Palm, Niger.....	lb.	.05½	—	.06
Peanut oil, crude, tank cars (f.o.b. mill).....	lb.	.06	—	.06½
Peanut oil, refined, in bbls.....	lb.	.10	—	.10½
Rapeseed oil, refined in bbls.....	gal.	.86	—	.88
Rapeseed oil, blown, in bbls.....	gal.	.92	—	.94
Soya bean oil (Manchurian), in bbls. N. Y.....	lb.	.07½	—	
Soya bean oil, tank cars, f.o.b., Pacific coast.....	lb.	.04½	—	

FISH

Light pressed menhaden.....	gal.	\$0.42	—	\$0.43
Yellow bleached menhaden.....	gal.	.45	—	
White bleached menhaden.....	gal.	.48	—	
Blown menhaden.....	gal.	.80	—	

Miscellaneous Materials

All f.o.b. New York Unless Otherwise Stated

Barytes, ground, white, f.o.b. Kings Creek, S. C.....	net ton	\$24.00	—	30.00

Industrial

Financial, Construction and Manufacturers' News

Construction and Operation

California

LOS ANGELES—The American Aluminum Products Co., 717 Van Nuys Bldg., recently incorporated, has acquired property aggregating about 5 acres at Burbank, near Los Angeles, a site for the erection of a new plant, to consist of a number of 1-story buildings. Preliminary plans are under way. William E. Dursten is president and Elwell D. Moore representative.

PASADENA—The Kahler Sprinkler & Brass Mfg. Co., 367 South Fair Oaks Ave., will build a 1-story addition to its plant to be equipped as a brass foundry.

RICHMOND—Charles J. Hurrell, New Hampton, Ind., is negotiating with the local Chamber of Commerce for a site for the erection of a new plant for the manufacture of window glass. Mr. Hurrell at one time operated a plant at Sacramento, Cal., but later sold the property. E. M. Downer and H. A. Johnston of the Chamber of Commerce are handling the details of the proposition.

REDWOOD CITY—The American Manganese Products Co. is reported to have purchased the local plant of the Aniline Dye Works, and will continue to operate the property.

WEST BERKELEY—John Lucas & Co., Inc., 322 Race St., Philadelphia, Pa., has acquired the local plant of the Glidden Co., manufacturer of paint, known as the Heath-Milligan unit, and will use the property for a branch plant for the manufacture of paint, varnish, etc.

SAN MATEO—The Minerals & By-Products Co., Denver, Col., is negotiating with the local Chamber of Commerce for a suitable site for the erection of a new plant. J. J. McGrath is president of the Chamber of Commerce and Daniel C. Imboden manager.

Connecticut

NORWALK—Charles H. Harris, president of Charles H. Harris, Inc., is planning for the erection of a new plant on property recently acquired on Main St., for the manufacture of glass for automobile windshield service. It will be 1-story, brick, and is estimated to cost about \$65,000.

NEW HAVEN—The National Folding Box Co. has taken bids for the erection of a new building at its plant on James St. Westcott & Mapes, Inc., New Haven, is engineer.

Delaware

WILMINGTON—The Hercules Powder Co. has received permission from the United States District Court to acquire the physical properties and assets of the Aetna Explosives Co.

Florida

WAUCHULA—W. G. DeVane, Trilby, Fla., and associates are planning for the erection of a new local fertilizer manufacturing plant to cost about \$30,000 with equipment. J. B. Foreman, Vinnea, Ga., is also interested in the project.

CANAL POINT—The Florida Sugar & Food Products Co. has acquired property consisting of about 700 acres of land, and plans for the erection of a large sugar mill.

Illinois

CHICAGO—The Aetna Porcelain Enameling Co., 4701 Augusta St., has broken ground for the erection of a 1-story plant addition to cost about \$10,000, to be located at Augusta St. and Kilpatrick Ave.

Indiana

INDIANAPOLIS—The Standard Oil Co. of Indiana has plans under way for the erection of a new oil refinery at Glenrock. Pressure stills will be installed to handle

the residue from the plant of the Mutual Refining & Producing Co., which is also arranging for plant enlargements. The latter company is a subsidiary of the Elk Basin Consolidated Petroleum Co.

Maryland

FROSTBURG—The Big Savage Fire Brick Co. is planning for the rebuilding of its power plant and other buildings, recently destroyed by fire, with loss estimated at about \$25,000.

FREDERICK—The O. J. Keller Lime Co. has commenced the construction of a new plant for the production of hydrated lime. The machinery will be arranged with individual motor drive. A lime storage building will also be erected. Richard K. Meade & Co., 13 East Fayette St., Baltimore, Md., are engineers for the work.

BALTIMORE—The new local plant of the American Sugar Refining Co., 117 Wall St., New York, now in course of construction, will require about 12 months to bring to completion. It will occupy a site of about 20 acres of land in the heart of the city, and is estimated to cost in excess of \$5,000,000.

BALTIMORE—The American Foundry & Mfg. Co., South St., is planning for the erection of an addition to its foundry; a machine shop will also be built. The extensions are estimated to cost about \$40,000. The company recently increased its capital to \$200,000. John E. Shell, Jr., is manager.

Missouri

KNOB NOSTER—The Johnson County Brick Co., recently reorganized with a capital of \$125,000, is planning for additions in its plant to increase the capacity from 30,000 to 50,000 bricks per day. A number of new kilns will be constructed at the plant, and considerable new machinery installed in the different operating departments. W. J. Mayes is president, and Frank L. Mayes treasurer.

RICHARDS—William E. Willis and W. J. Smiley of this place are organizing a company to build a new oil-refining plant in the vicinity of Springfield, Mo., with initial daily capacity of about 500 bbl. The plant will be erected on the unit type, and is estimated to cost about \$100,000.

SPRINGFIELD—The Forster Mfg. Co., recently incorporated with a capital of \$300,000, is planning for the erection of a new plant for the manufacture of cleaners, polishes and kindred products. The initial daily capacity will be about 15 tons of material. T. E. Forster, Neosho, Mo., is president, and D. D. Neblett secretary and treasurer.

New Jersey

WASHINGTON—The Washington Porcelain Co., manufacturer of electrical porcelain products, has completed the erection of two additions to its plant for increased operations, 50x96 ft. and 20x50 ft. respectively.

NEWARK—The Schenck & Schliete Co., Nesbitt St., manufacturer of paper boxes and containers, has leased a portion of the Quimby Bldg. at 21-39 Division St., totaling about 30,000 sq. ft. of floor space, for the establishment of a new plant.

NEWARK—The Reeves Mfg. Co. has broken ground for the erection of a new 2-story brass foundry at 318-26 Passaic St. to cost about \$12,000. Arthur D. Reeve heads the company. Fitzsimmons & Richards, 207 Market St., are architects.

New York

BROOKLYN—Constant A. Benoit, operating a chemical manufacturing plant on Jerome Ave., has made application to the Board of Appeals for permission to build a new 3-story plant at 1702-18 Avenue Y, corner East Seventeenth St., for the manufacture of colors, enamels, varnishes and kindred products.

BROOKLYN—The Basic Chemical Corporation of America, 77 Seventh Ave., has leased property at 847 Union St. for a period of 5 years for a manufacturing plant.

LONG ISLAND CITY—Mayer & Lowenstein, Vernon Ave. near Bodine St., manufacturer of varnishes, etc., have awarded a contract to M. J. Irwin & Sons, 19 Hulst St., for the erection of a 1-story addition to cost about \$17,000.

NEW YORK—The Cuba Cane Sugar Corp., 117 Wall St., is planning for the erection of a new sugar mill in eastern Cuba, with initial capacity of about 250,000 bags. At a later date extensions will be erected to double this output. The company is now operating 17 estates in Cuba.

NEW YORK—The Talc Products Co., 7 Hanover St., manufacturer of talc, soapstone, etc., is planning for the erection of a new mill in the vicinity of its present plant at Glendon, N. C. The proposed plant will have an initial capacity of about 100 tons of material daily. The company will also open up additional mining properties in this section.

NEW YORK—The International Petroleum Co., 120 B'way, has acquired an island in the Harbor of Barranquilla, Colombia, S. A., on the Magdalena River, as a site for the erection of a new oil refinery, to have a daily capacity of about 25,000 bbl., and which output will be increased at an early date. The company is now building a refining plant about 400 miles up the Magdalena River, to have an initial capacity of 2,000 bbl. per day. It is expected to have this latter plant ready for service at an early date.

Ohio

CINCINNATI—The Rossa-Ratliff Chemical Co. has leased a 5-story building for the establishment of a new plant, replacing its works recently destroyed by fire.

Oklahoma

OKMULGEE—The Okmulgee Brick Co. is perfecting plans for the erection of a new local plant for the manufacture of paving brick and other burned clay products. R. E. Buckles is engineer.

Pennsylvania

PHILADELPHIA—The Crew Levick Co., 111 North Broad St., operating local oil refineries with total capacity of about 80,000 bbl. per month, has arranged for a bond issue of \$1,500,000, a portion of the proceeds to be used for extensions, betterments and general operations. The company is a subsidiary of the Cities Service Co., 60 Wall St., New York.

SCRANTON—Fire May 5 destroyed the plant of the Diamond Paint & Oil Co., Seventh St., with loss estimated at about \$125,000. It is said that the factory will be rebuilt.

Utah

MARYSVALE—The Industrial Potash Corp., Rockford, Ill., recently organized with a capital of \$30,000,000, has plans under way for the erection of a large plant at Marysvale, for the manufacture of potash, fertilizer specialties and affiliated products. Potassium sulphate will be a primary feature of production. The new plant will have a capacity of about 10,000 tons of material per day, and with the development of raw material properties in this section is estimated to cost about \$1,000,000. The company is headed by Jacob H. Krause and Ross P. Beckstrom, Rockford; and Floyd Bergland, Marysvale. It is represented by Louis Grollman, 111 West Monroe St., Chicago, Ill.

Virginia

HOPEWELL—The Hopewell Chemical Co., recently organized with a capital of \$500,000, will soon commence production at its local plant for the manufacture of sodium sulphate and kindred specialties. A new building will be erected at an early date for increased capacity. The residue from nitre lakes near Roanoke, Va., will be used at the plant.

AQUIT STATION—The Fer-Sul Chemical Corp., has had plans prepared by the National Laboratories, 1313 H St., N. W., Washington, D. C., for the erection of a new plant for the production of sulphuric acid; the initial works will have a capacity of about 65 tons.

Washington

SPOKANE—The Western Soap Co., Ltd., has preliminary plans under way for the erection of a new plant at Sinto and Ash Sts. It will be 3-story, 92x100 ft., and is estimated to cost about \$100,000 with machinery. Frank E. Irvine is president and manager.

Capital Increases, Etc.

THE QUEEN CITY BRICK & TILE Co., Cumberland, Md., manufacturer of brick, tile and other ceramic products, has filed notice of increase in capital from \$100,000 to \$200,000.

THE COSMO CHEMICAL Co., Muncie, Ind., has filed notice of dissolution under state laws.

THE UNITED ZINC SMELTING CORP., Eddyville, N. Y., has filed notice of increase in active capital from \$3,000,000 to \$4,000,000, with \$1,000,000 in preferred stock and 60,000 shares of common stock, no par value.

THE VIRGINIA ORES CORP., Lynchburg, Va., has filed notice of increase in capital from \$750,000 to \$1,500,000. S. S. Johnson is vice-president.

THE DECATUR BRASS WORKS, Decatur, Ill., has increased its capital from \$100,000 to \$200,000.

THE BOLIVAR CLAY PRODUCTS Co., Pittsburgh, Pa., has filed notice of increase in capital from \$100,000 to \$225,000.

New Companies

THE LIBERTY LEATHER CORP., Boston, Mass., has been incorporated with a capital of \$150,000 to manufacture leather products. William J. Fallon, Sr., is president; and William J. Fallon, Jr., 938 South St., Roslindale, Mass., treasurer.

THE WONDER CHEMICAL Co., Trenton, N. J., has been incorporated with a capital of \$100,000 to manufacture chemicals and chemical byproducts. The incorporators are Filippo Benedetti and Melchior F. Morton, Trenton.

THE PARAGON REFINING Co. OF NEW YORK, Buffalo, N. Y., has been incorporated with a capital of \$100,000 to manufacture petroleum and other oil products. The incorporators are A. S. Matthews, I. C. Taber and C. A. Ulsh. Kent, Cummings & Means, Dun Bldg., represent the company.

THE ILLINOIS-WISCONSIN CONCRETE PIPE & TILE Co., 112 West Adams St., Chicago, Ill., has been incorporated with a capital of \$50,000 to manufacture concrete products. The incorporators are George B. Harker, A. S. Sorenson and W. C. Whitcomb.

THE LITTLE TAMPICO PETROLEUM Co., Los Angeles, Cal., has been incorporated with a capital of \$1,000,000 to manufacture petroleum products. The incorporators are William A. Meyer, H. H. Everett and Frederick Haas. I. Henry Harris, 1127 Title Insurance Bldg., represent the company.

THE O-JOY CHEMICAL Co., Syracuse, N. Y., has been incorporated with a capital of \$25,000 to manufacture chemicals and chemical byproducts. The incorporators are F. L. Hogan, G. B. Stearns and H. B. Ansell, Burney Bldg.

THE WESTGARD SAW Co., 252 Empire Bldg., Seattle, Wash., has been incorporated with a capital of \$100,000 to manufacture circular saws with high-speed steel insertible teeth. A. D. Cross is secretary and treasurer.

THE SILENT PRODUCTS Co., Elizabeth, N. J., has been incorporated with a capital of \$125,000 to manufacture chemical specialties. The incorporators are Philip P. Scherer, Augustus J. and Welcome W. Bender, 208 Broad St.

THE SOLVENT PRODUCTS Co., Boston, Mass., has been incorporated with a capital of 400 shares of stock, no par value, to manufacture soap, dyestuffs, etc. Charles R. LaRose is president, and Edward W. Dougher, 21 Hyland St., Dorchester, Mass., treasurer.

THE HUDSON CEMENT PRODUCTS CORP., White Plains, N. Y., has been incorporated with a capital of \$200,000 to manufacture cement products. The incorporators are A. D'Elie, L. E. Karle and W. G. Brown, Woolworth Bldg., New York.

THE LYNX SANITARY Co., 116 Market St., Newark, N. J., has filed notice of organization to manufacture chemical products, disinfectants, etc. Lincoln Arndt, 336 Belmont Ave., heads the company.

THE QUAKER CITY LEATHER Co., Philadelphia, Pa., has been incorporated with a capital of \$25,000 to manufacture leather products. C. W. Toebe, 6448 Woodbine Ave., is treasurer.

THE SARDONYX MFG. Co., Dallas, Tex., has been incorporated with a capital of \$50,000 to manufacture soaps and kindred products. The incorporators are J. E. Bryant, E. Morley Page, Dallas; and William H. Herring, Houston, Tex.

THE PENN PAPER Co., Erie, Pa., has been incorporated with a capital of \$50,000 to manufacture and deal in paper products. John F. Young, 604 East Twenty-first St., is treasurer.

THE SPRINGFIELD BRONZE Co., Springfield, Mass., has been incorporated with a capital of \$50,000 to manufacture brass and bronze products. Joseph R. Gould, 125 Ohio Ave., West, is president and treasurer; Robert S. Kneeland and Leonard Johnston are directors.

THE COLONIAL BRICK Co., Calvert Bldg., Baltimore, Md., has been incorporated with a capital of \$50,000 to manufacture brick and other burned clay products. The incorporators are William F. Bell, Edward T. Reisler and Albin Widoff.

THE M. FRENVILLE Co., New York, N. Y., has been incorporated with a capital of \$50,000 to manufacture leather products. The incorporators are M. Frenville, W. J. Delaney and L. G. Bernard. Price & Nathan, 19 Cedar St., represent the company.
